

The baking analogy of a OSI model.

(I will remember this pretty good I think because my girlfriend is a baker.)

- Physical layer(1): Bakers need their ingredients to start what they are making.

(For computers it would be wires and cables to connect them.)

-Data link layer(2): The product being baked is packaged, labeled and ready for consumers.

(For computers this is the process of figuring out where the information is going without messing up.)

-Network layer(3): The consumer has a GPS on the bakers shop to pick the product up.

(For computers, this is the process when the computers find the way to send information without messing up)

-Transport layer(4): The consumer has picked up the product successfully.

(for computers, the information was sent out without any mistakes)

-Session layer(5): The consumer is eating the product.

(for computers, data is being shared)

-Presentation layer(6): The product is looks very presentable and nice.

(for computers taking data from application layer to allow computers to process and presenting it to the other computers)

-Application layer(7): The product has maybe frosting, or decorations, depending on what's baked.

(for computers this is the computer's programs communicating with the internet overall)

The OSI model is made up of seven layers that are always communicating to allow the network to run smoothly. Each layer runs differently in terms of function, device(computer, router, firewalls), PDU (Data, packets, bits) and protocols. Application layer sends down data to presentation, to handle the data to allow computer to process and understand, then the data just keeps getting sent through the layers as they are working together to process the data. All seven layers have purpose in keeping the network smoothly if networking protocols adhere to the OSI model.
