

Post install tasks

Collin King

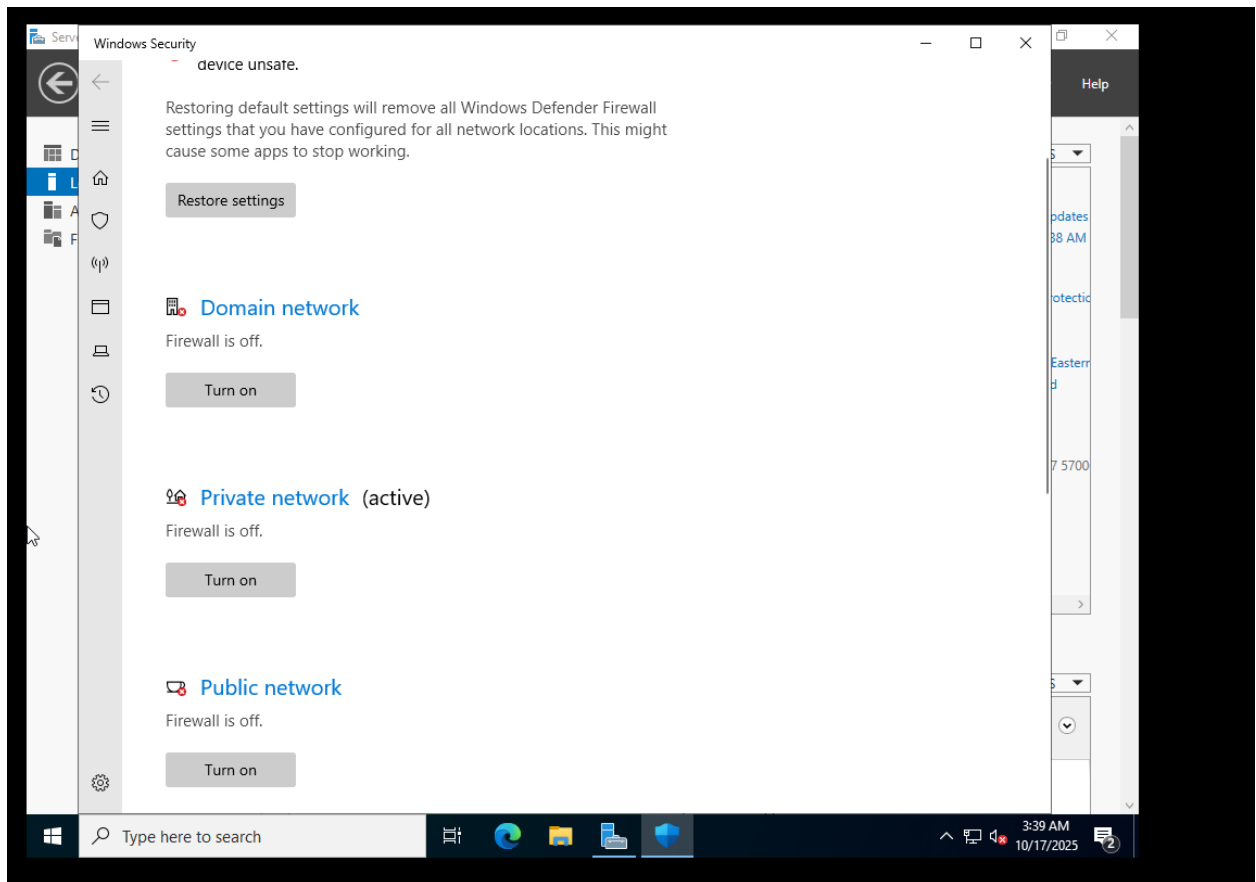

First I booted up VMware and powered on the server 2022 VM.

Logged in and let the server manager load up, went to local server on the left side then selected the hyperlink next to Time zone.

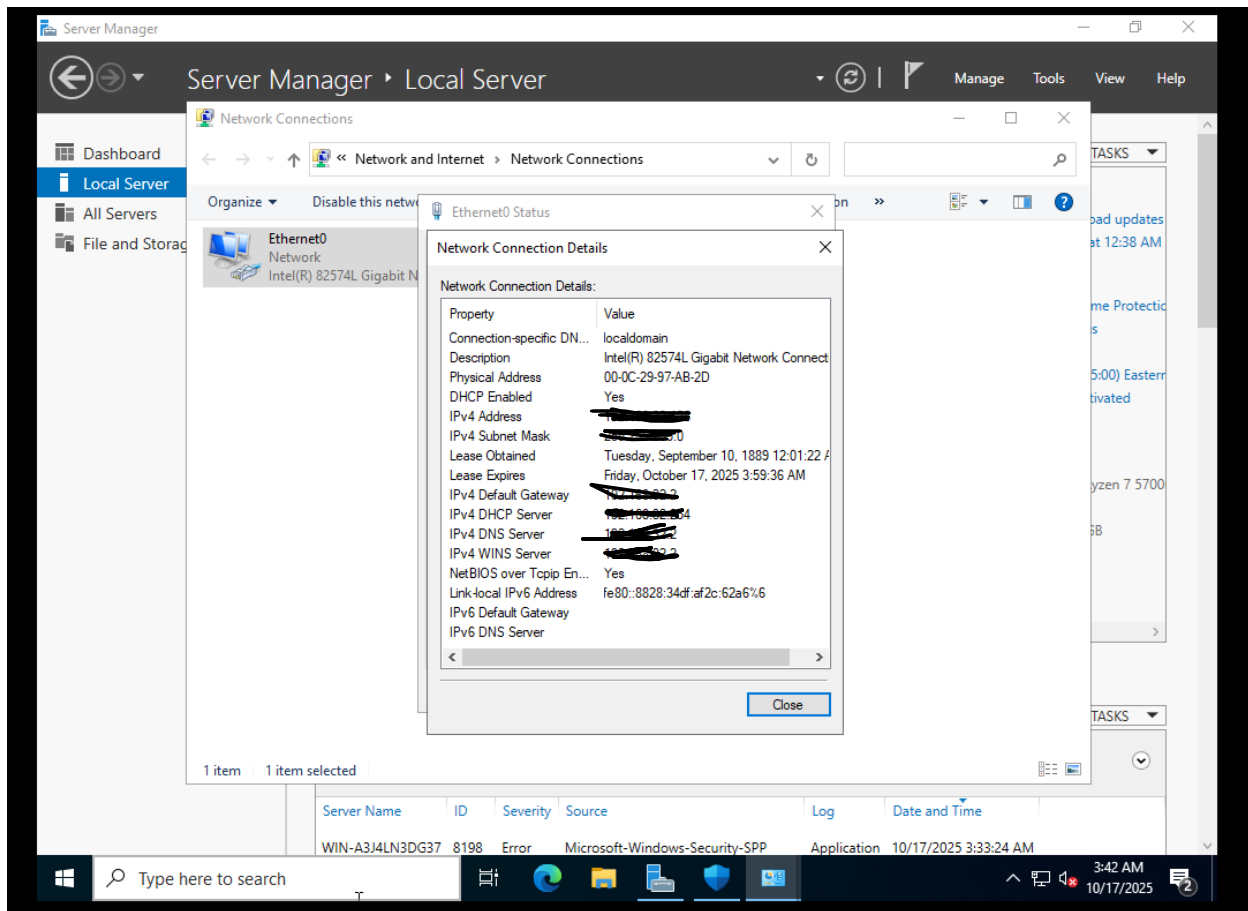

I then clicked change date and time, selected Eastern time zone, then clicked okay.

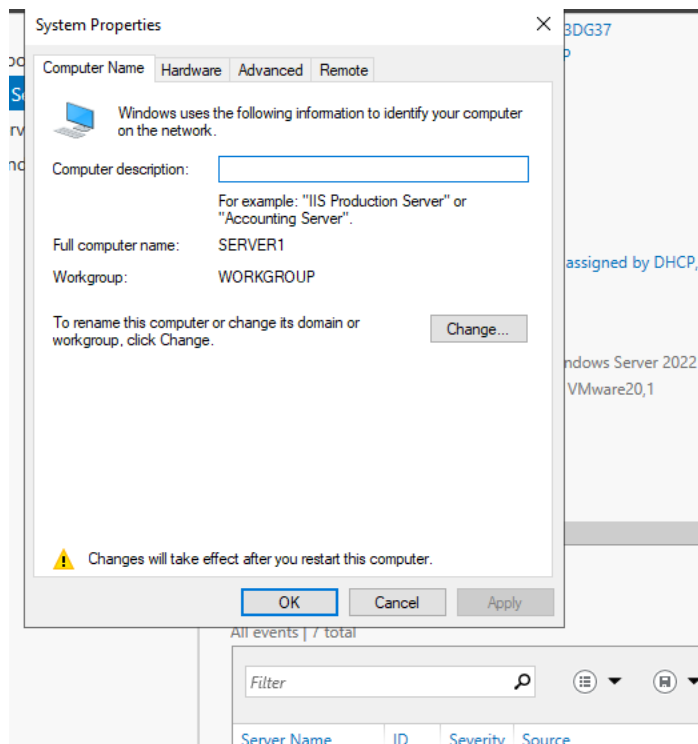

Back into the server properties I found the hyperlink “Private: On” for the firewall.

Going through Domain network, Private network, and public network I disabled firewalls

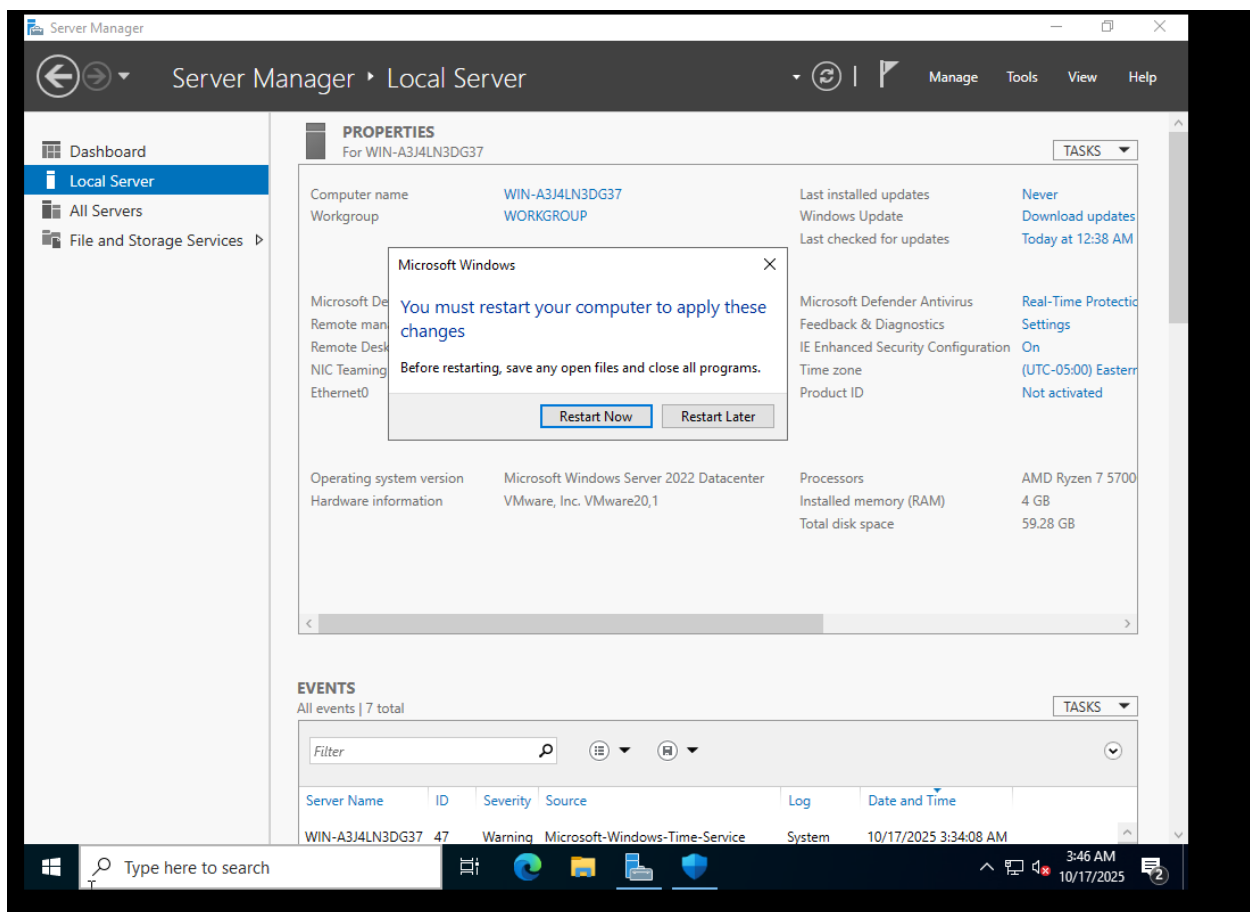

Again back to server properties, next to the ethernet adapter I clicked the hyperlink to bring me to network connections, I then right clicked to go to status. Went into the details menu and found the IPv4.

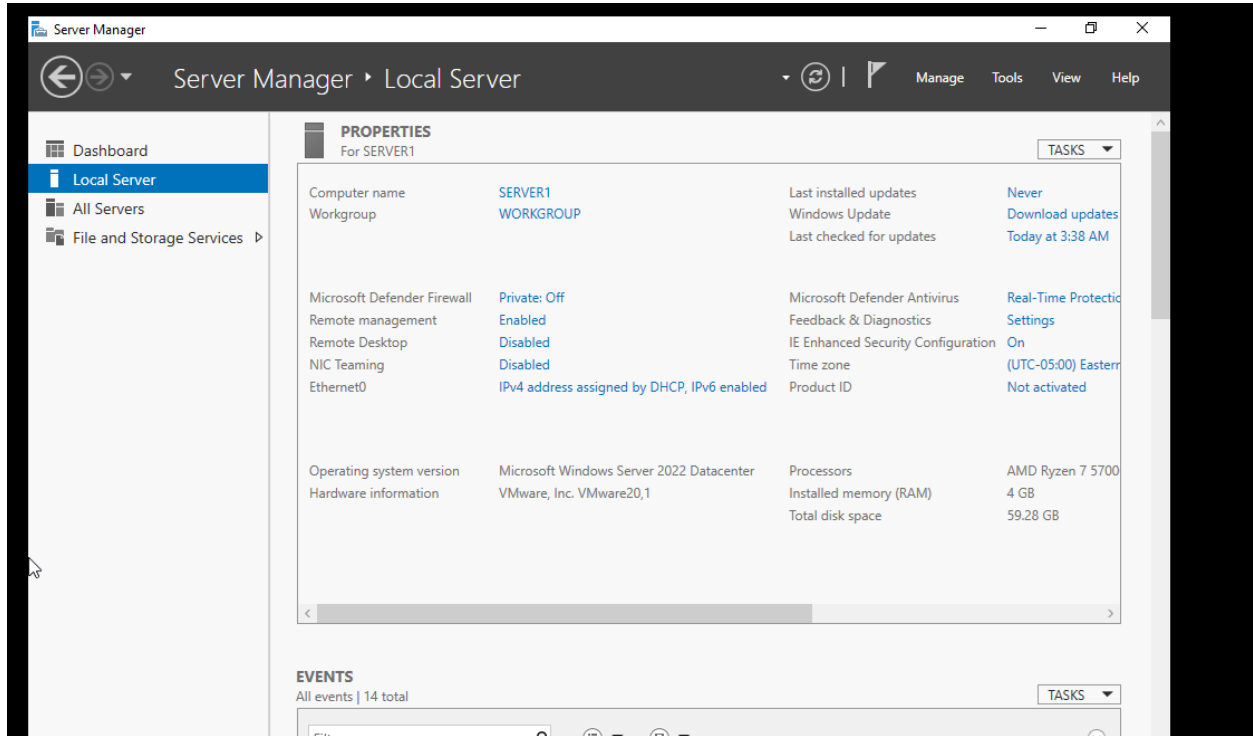

DCHP Enabled : Yes

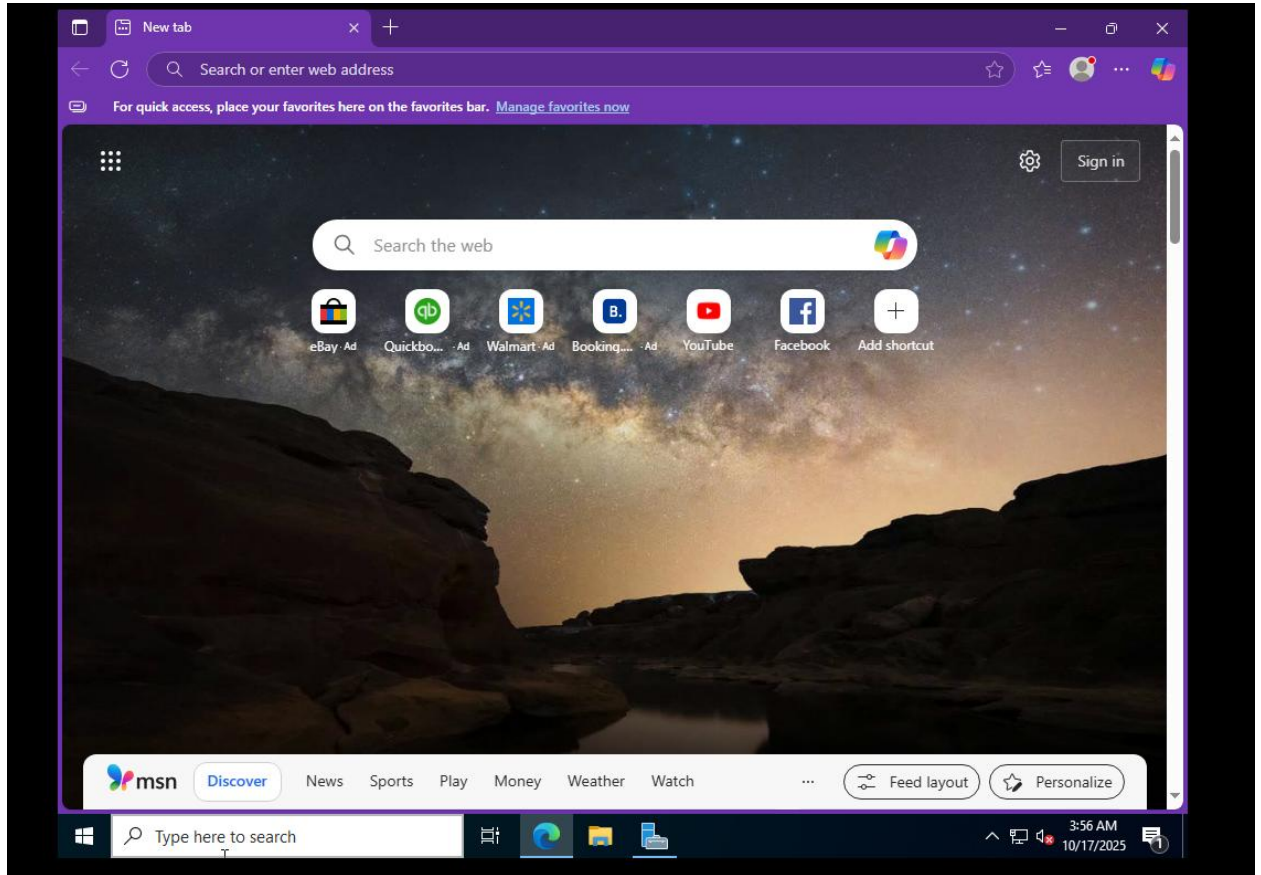

Closing out of network connections I then went back to the server properties, found computer name then clicked the hyperlink. I changed the computer name to Server 1. Click OK.

After clicking OK windows told me I must restart for changes to happen, so I restarted the VM.

Logged back into the server VM, let the server manager load, went back into the server properties then checked if the name was changed.

I then configured edge then moved on to the Updating Windows server lab.
