

Lab02 Install Collin King

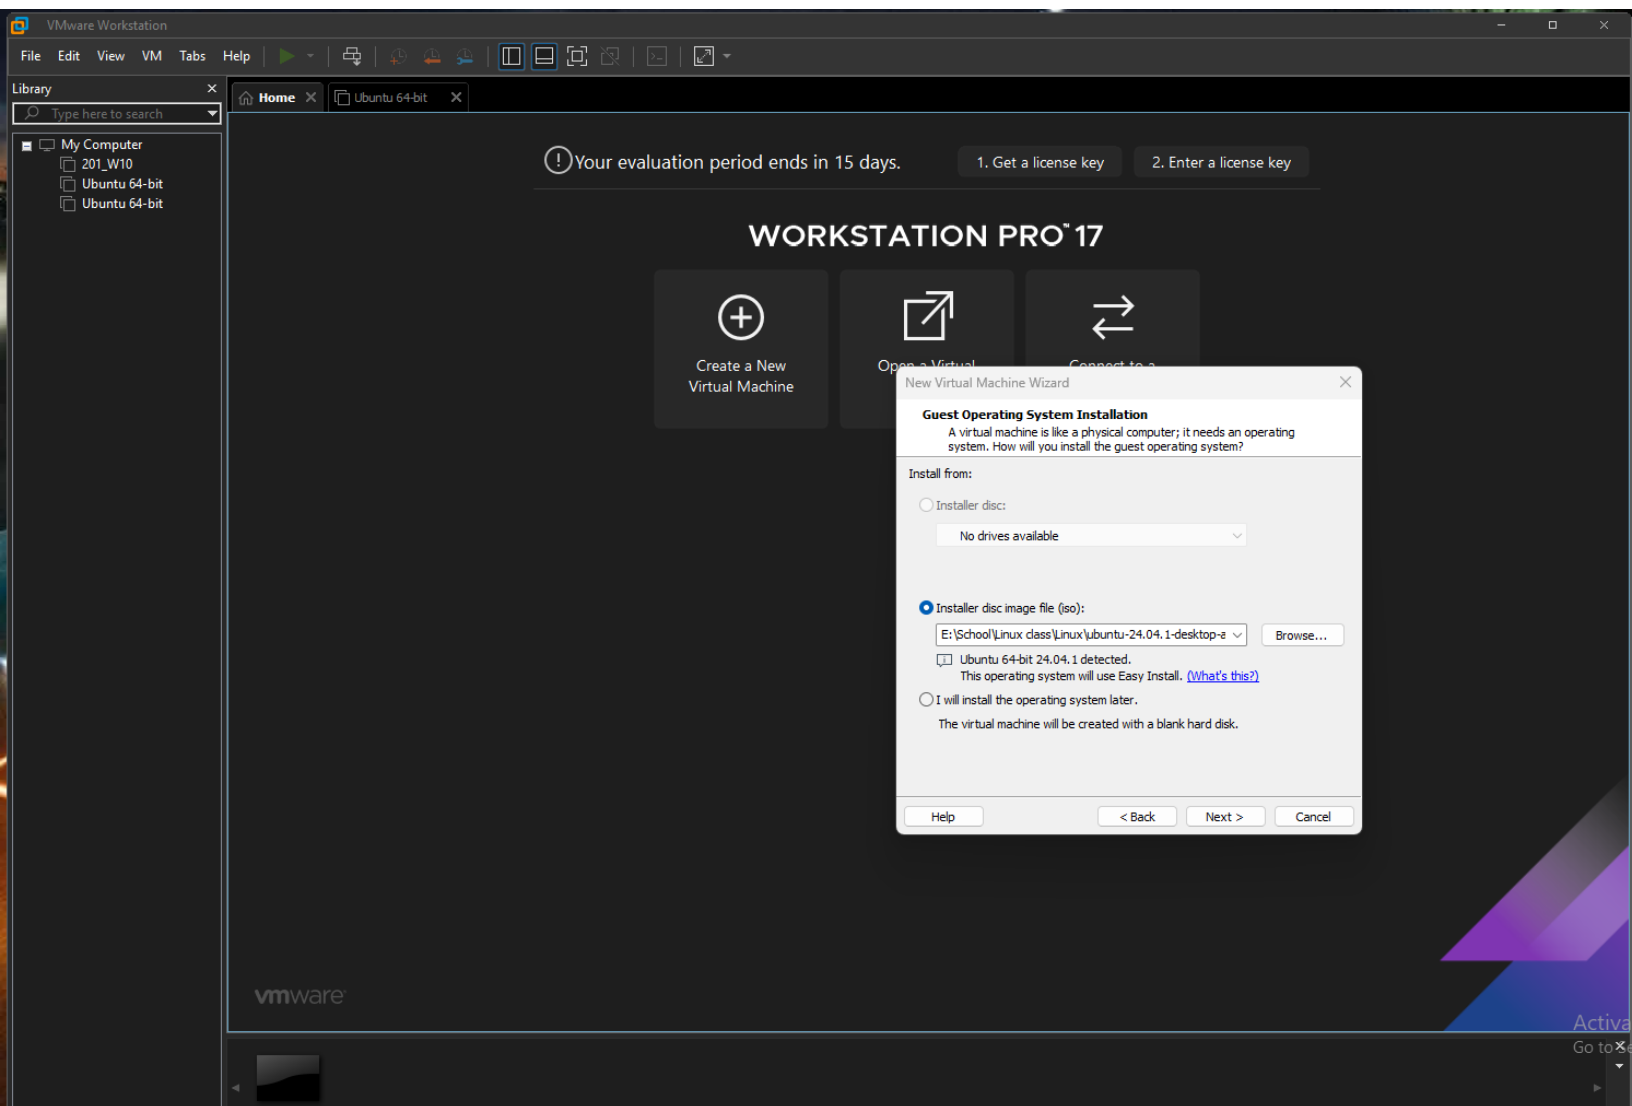

First open up VMWare! It appears I have an update for my program so ill go ahead and select “Download and Install”

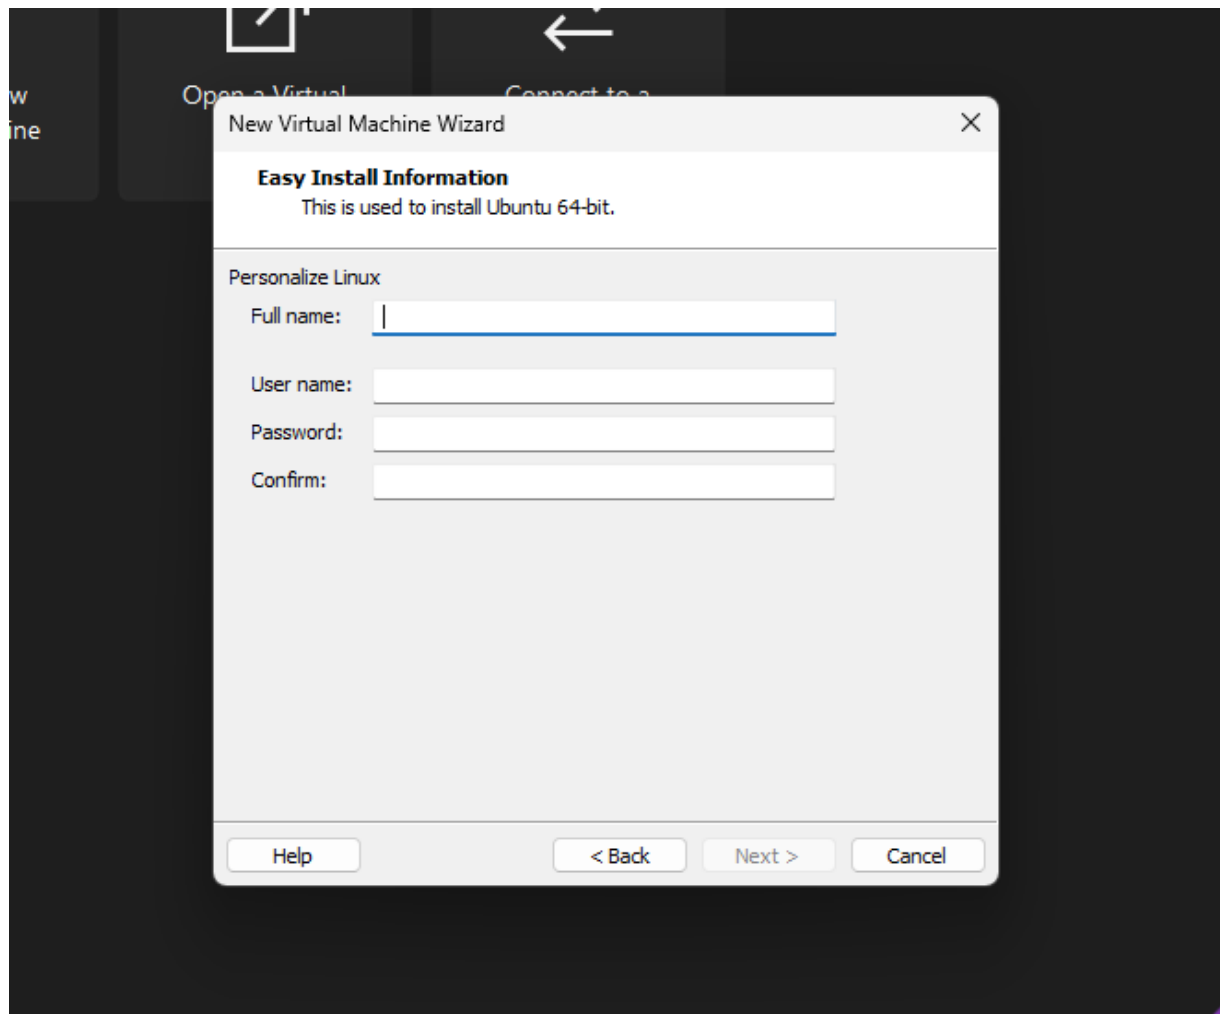

Let the program update and it should restart after updating!

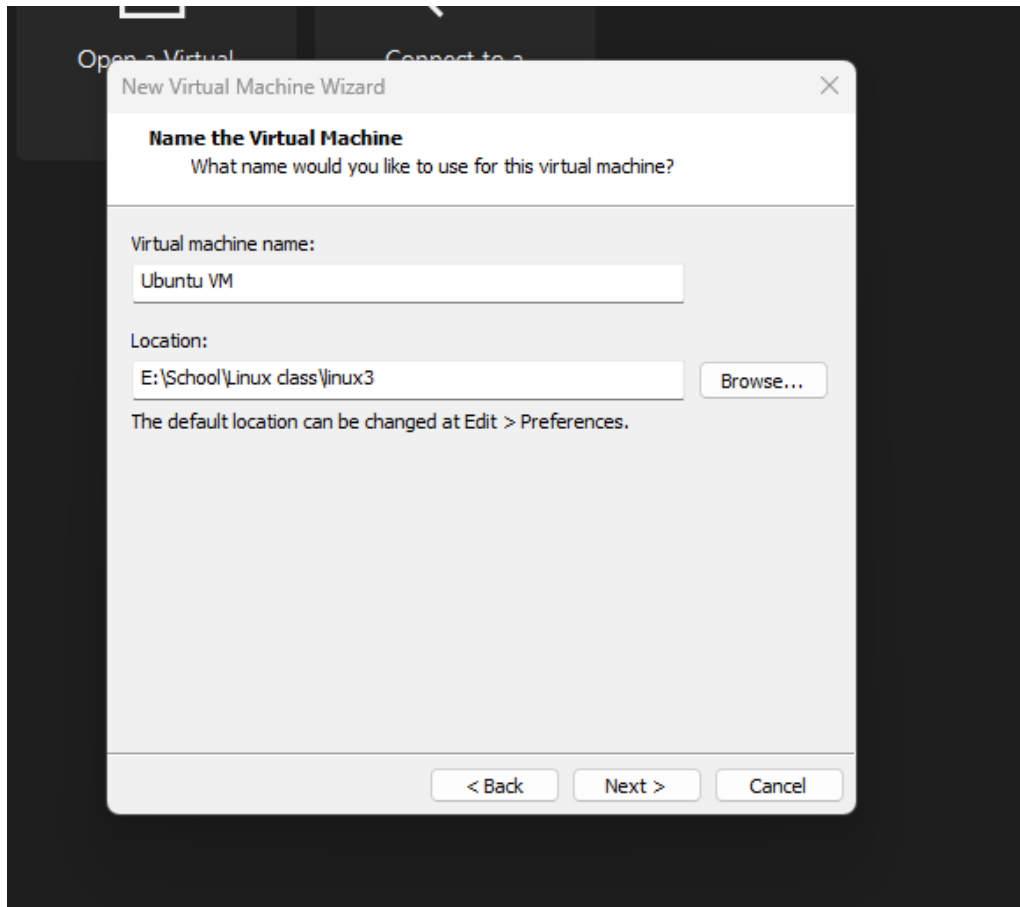

To begin installing, click the “Create a New Virtual Machine” button, you’ll notice there is two options, typical and custom. We are going to keep typical selected then click next at the bottom of the menu.

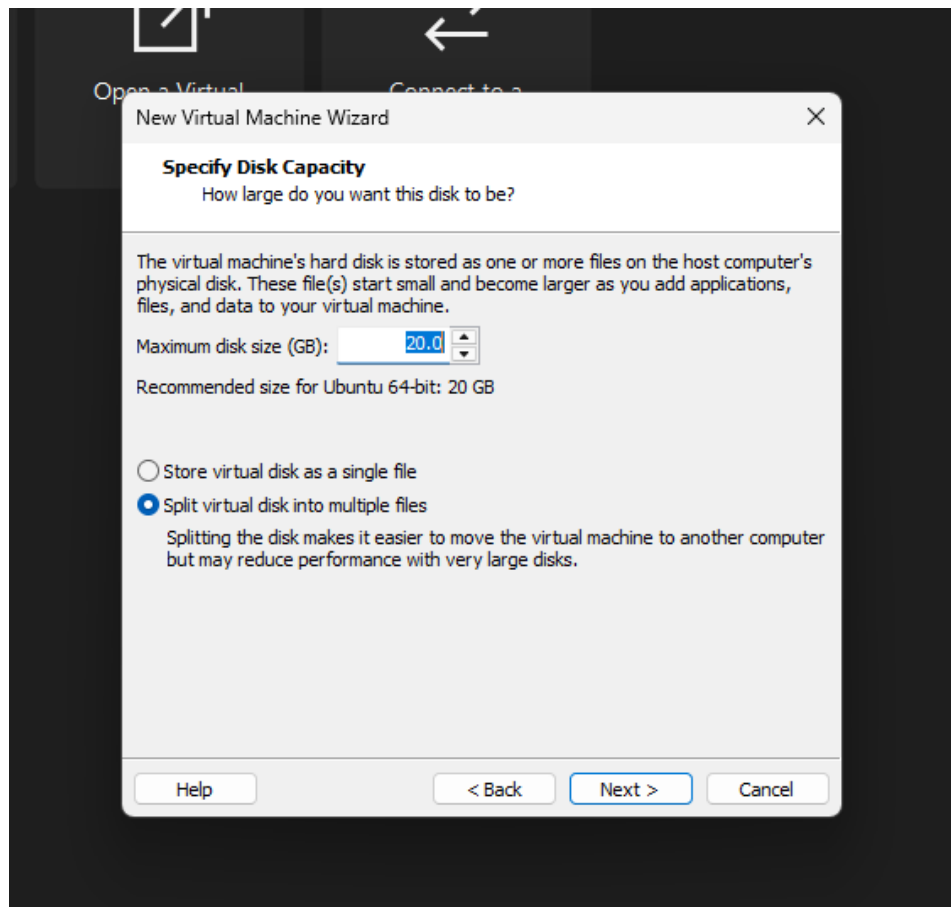

After clicking next, this menu appears asking for the install location of the ISO files, it would be a good idea to have a folder just for ISO files that have been installed to keep the files organized and you can easily find them. Select “Installer image disc file (iso)” then click browse next to that option to find the ISO file you need.

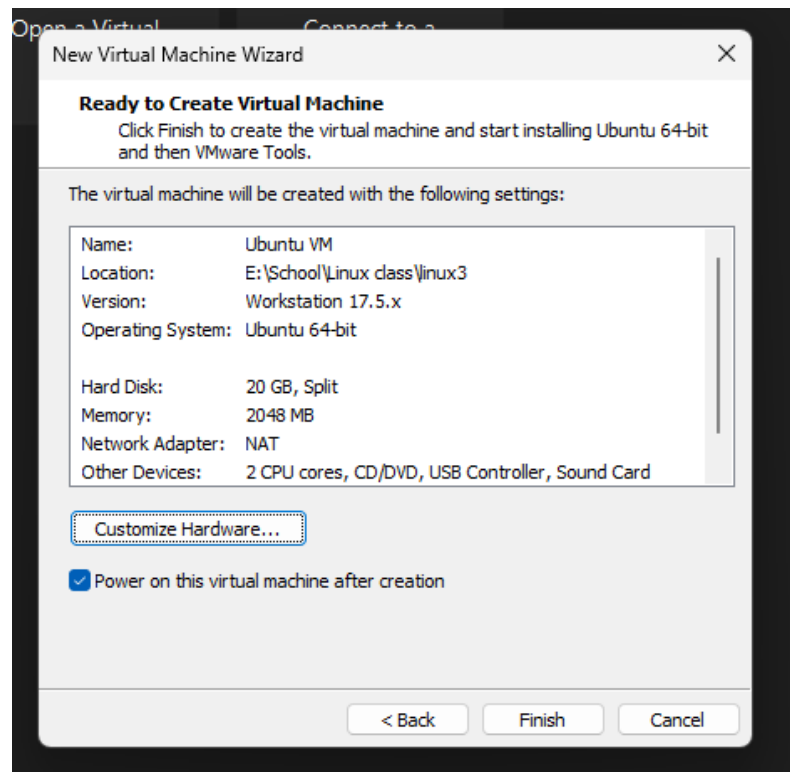

Click next after selecting the iso file, then fill out the forms for Linux.

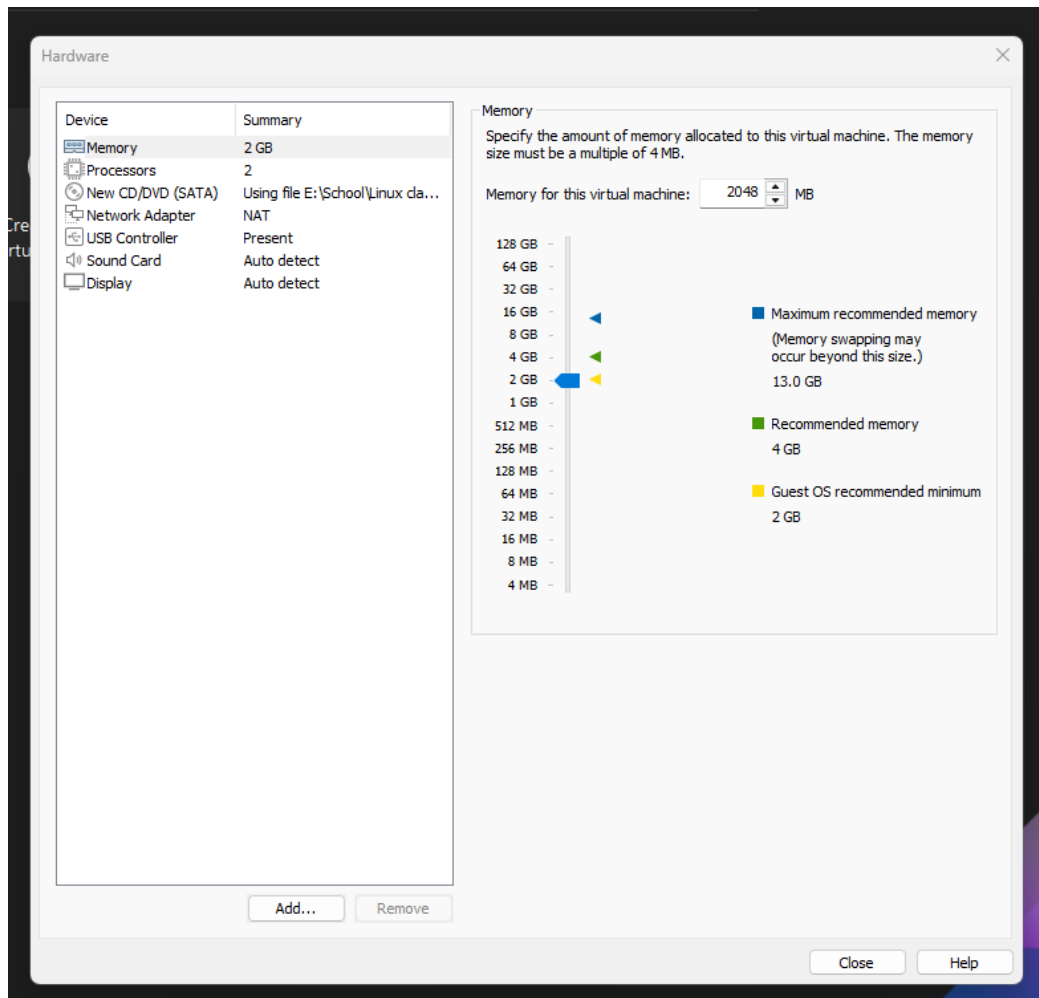

After filling out the forms click next at this screen I gave the VM a name and changed the file location.

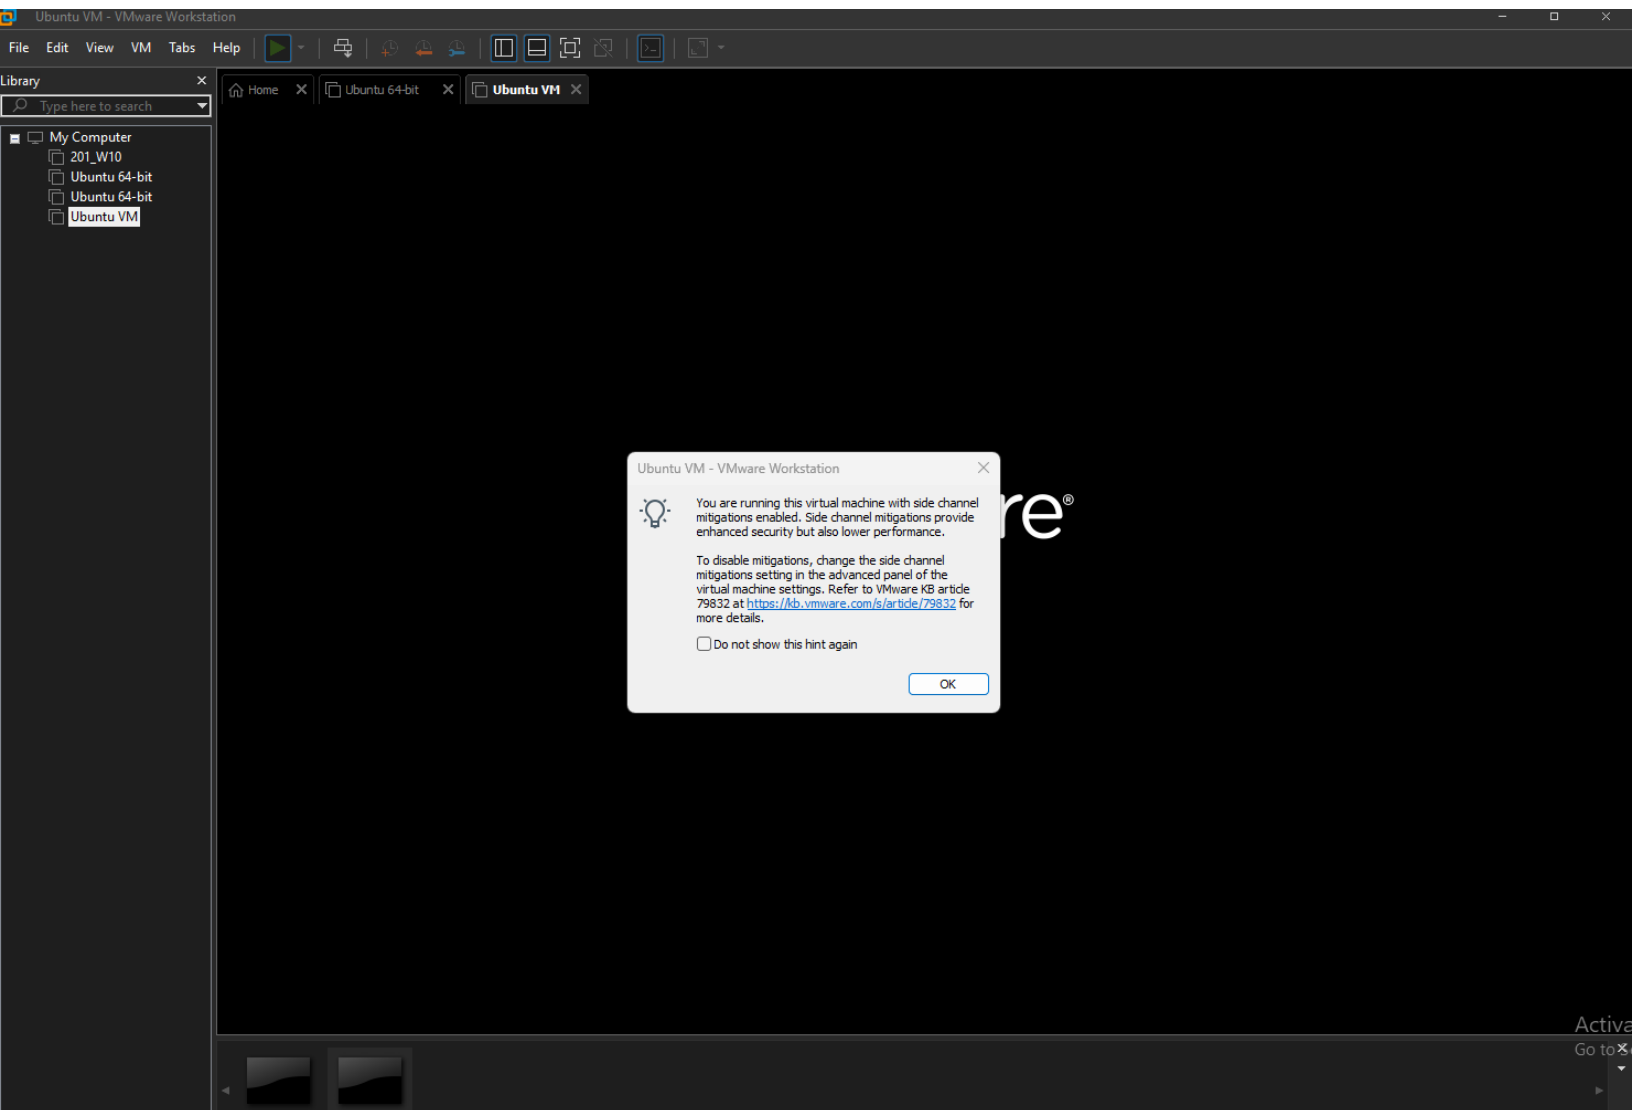

Click next after naming the VM, leave the disk space at 20.

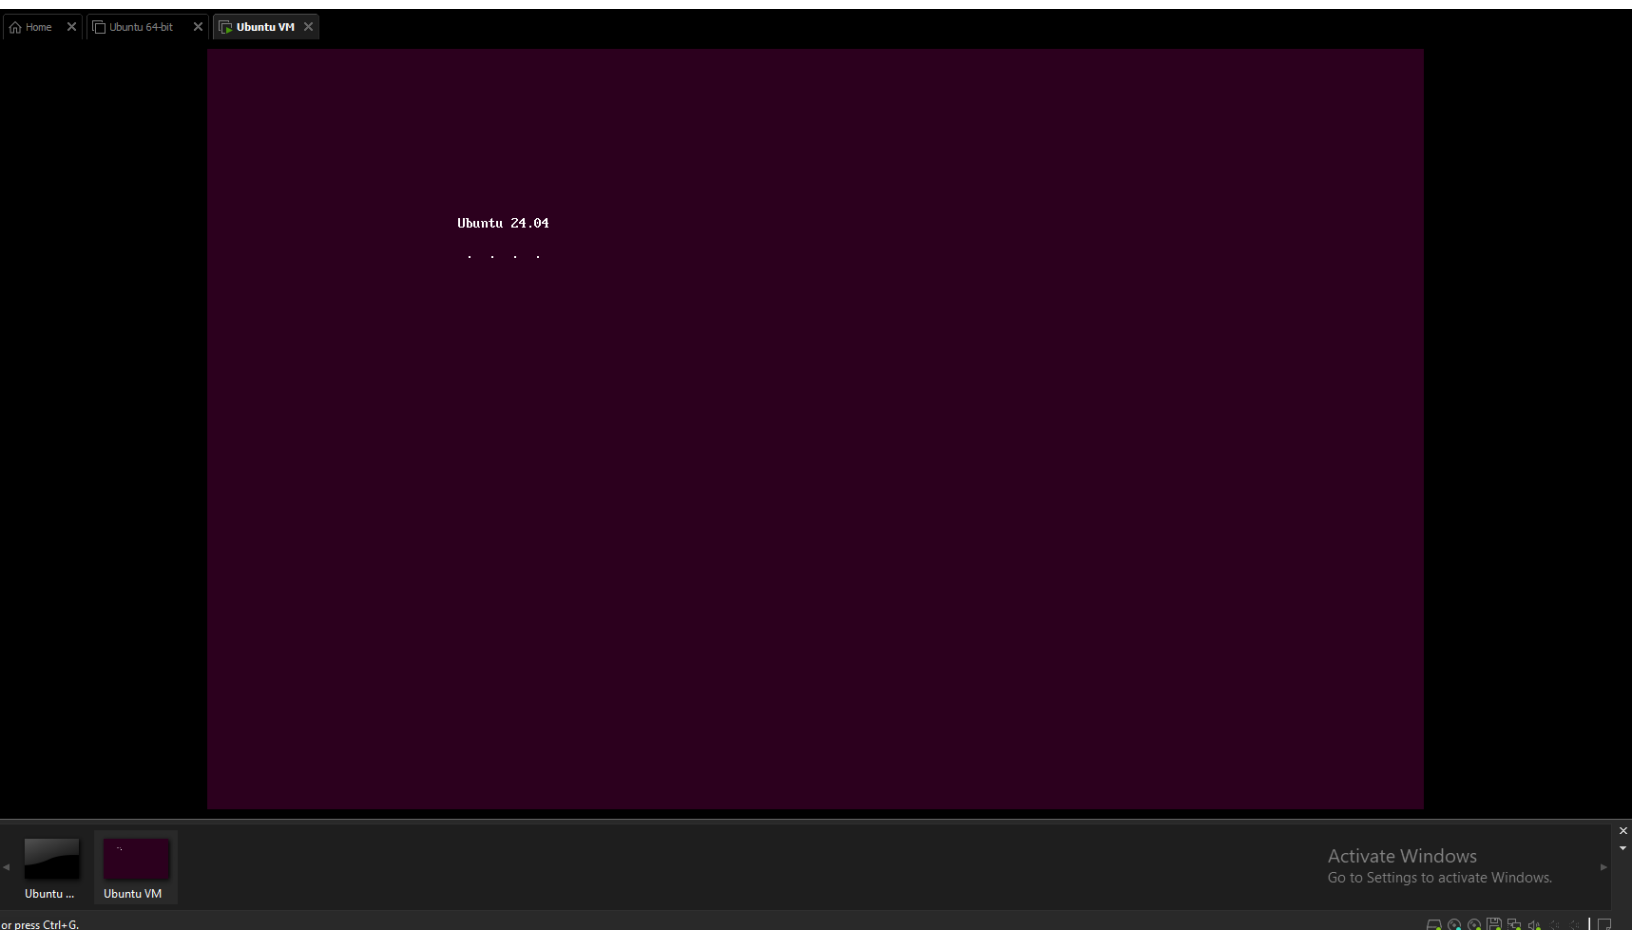

Click next then here you can look at the hardware of the VM

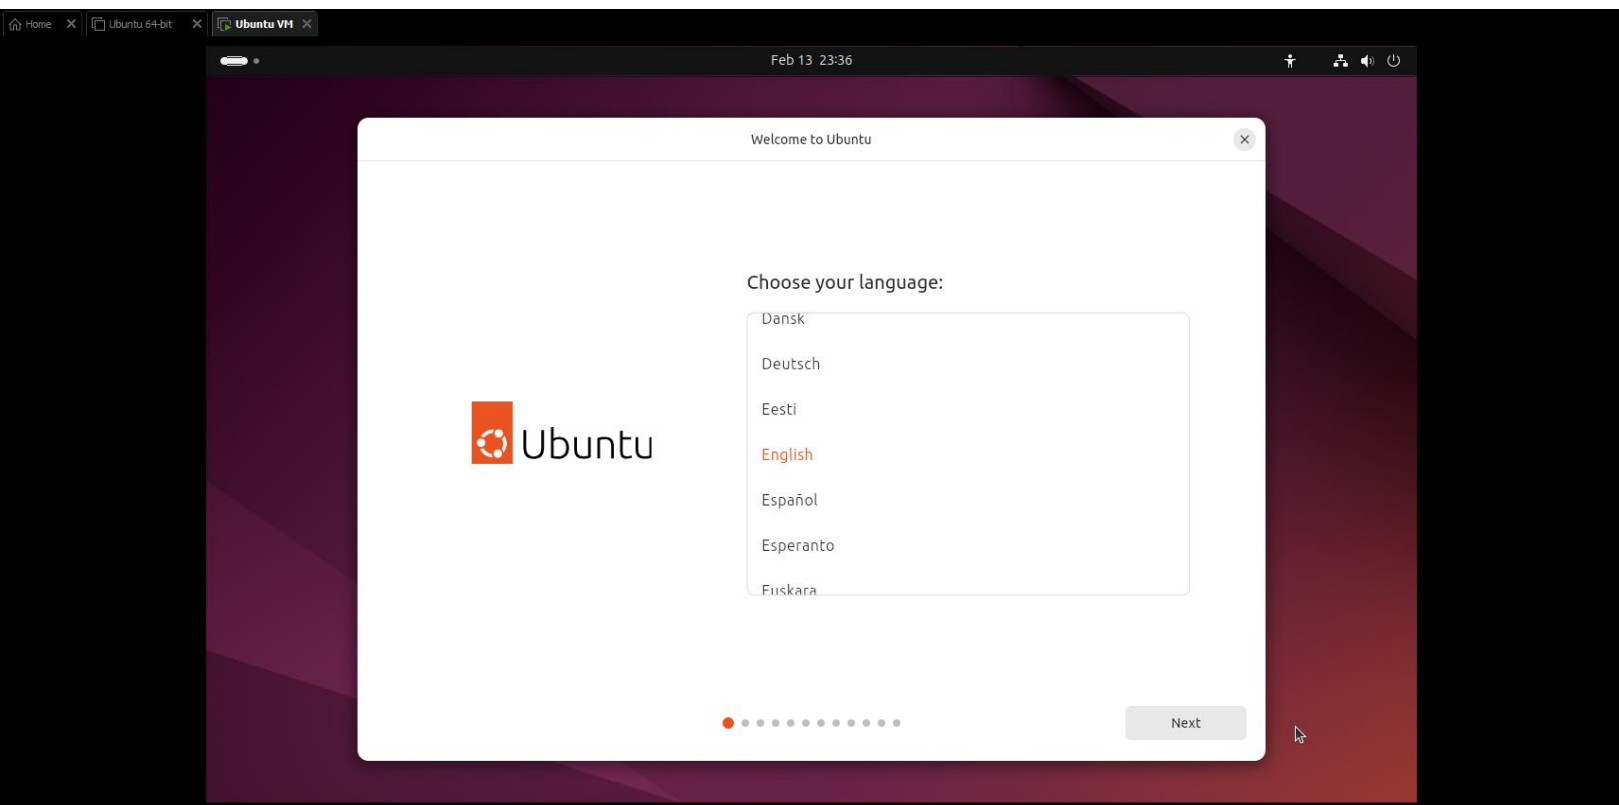

If you click customize hardware you'll be greeted with this screen. You can change the RAM the VM uses or anything hardware related you may need to change. Make sure NAT is selected for network adapter so we can have internet on the VM. After you're done with this menu, click close, you'll be brought back to the original hardware screen, then click finish.

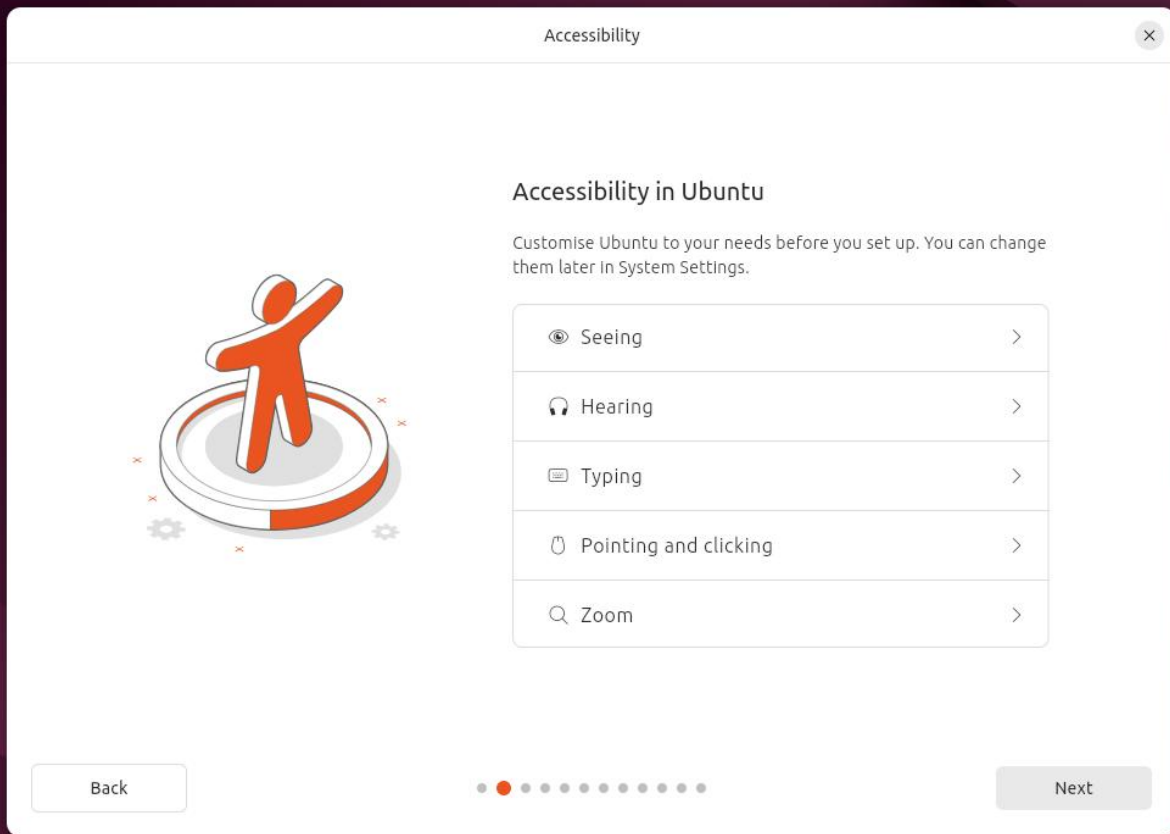

After selecting finish the installation will start, chances are this pop up will NOT occur for you as I have another VM tab opened , so I just click okay then it continues.

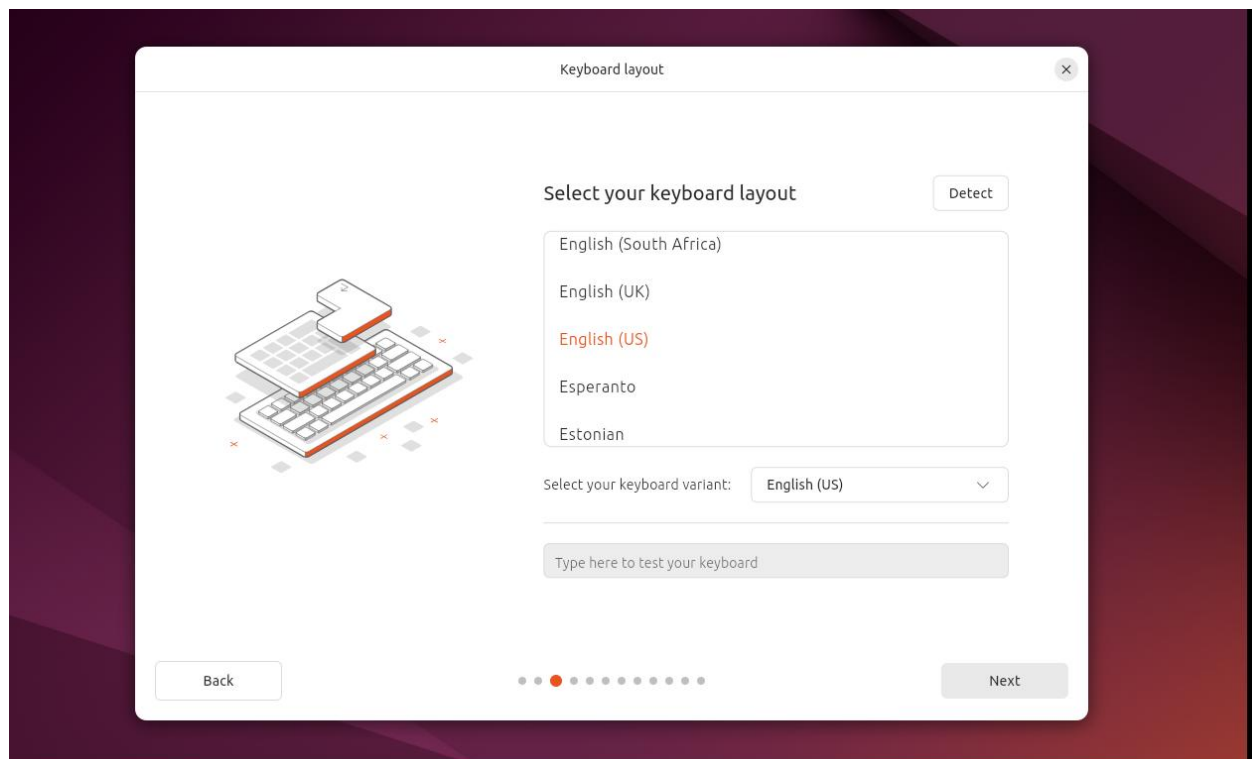

Linux will start up, then you'll see this screen, it just means its loading up. You will experience a black screen after this , then the Ubuntu installer will pop up after its done loading up.

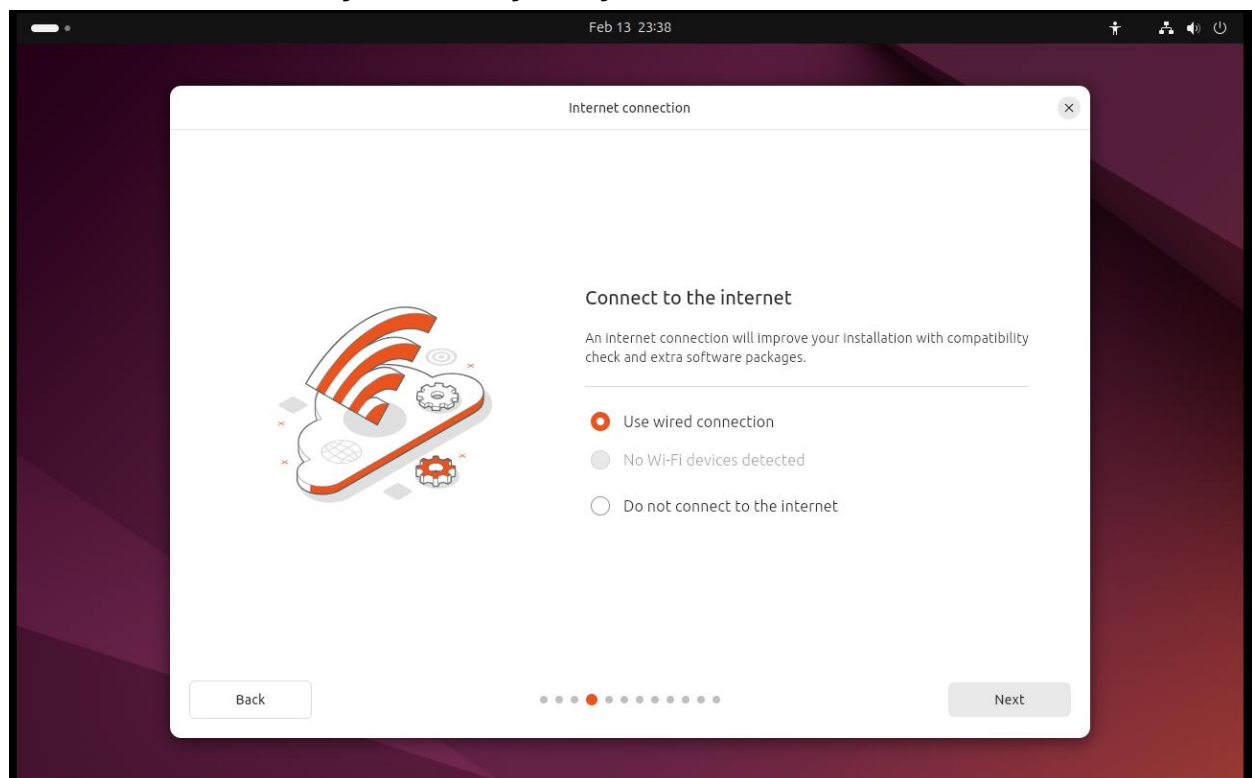

Here is the first screen of the installer! Select your language and click next.

Select Any accessibility settings you may need, then click next.

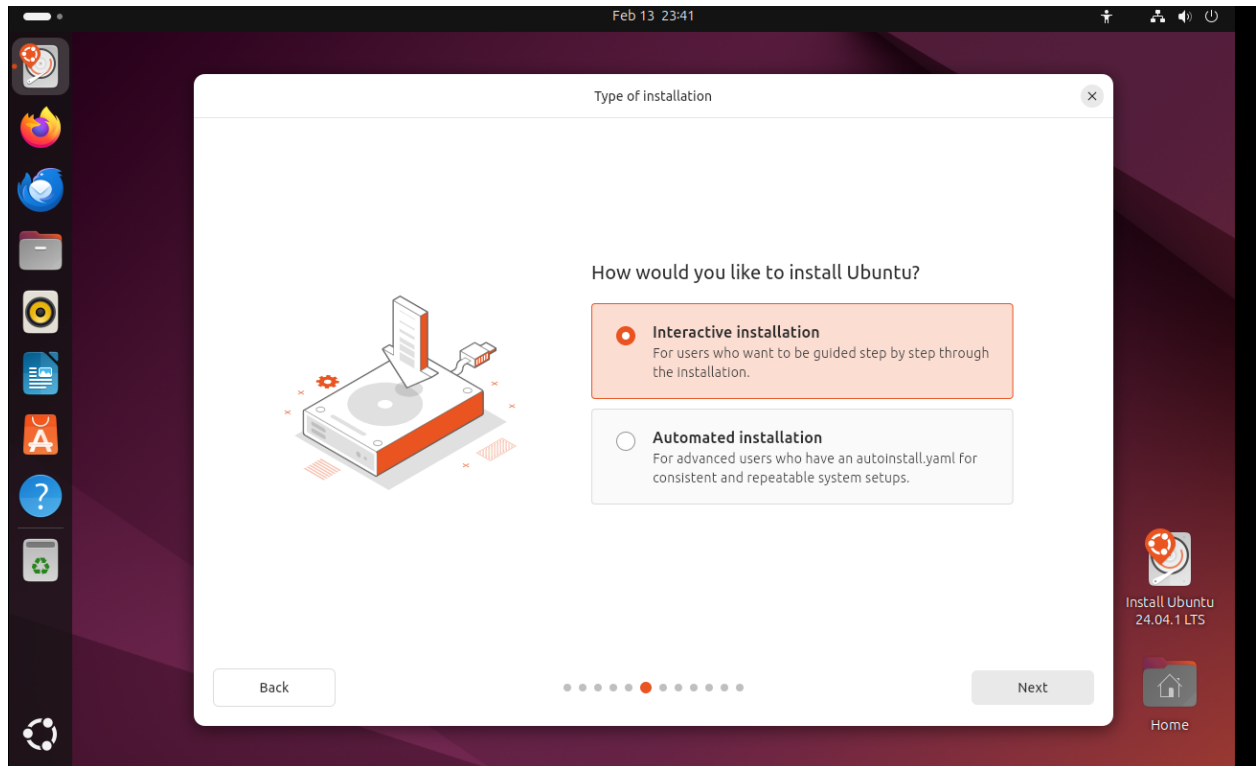

Select the keyboard layout you wish to use, then click next.

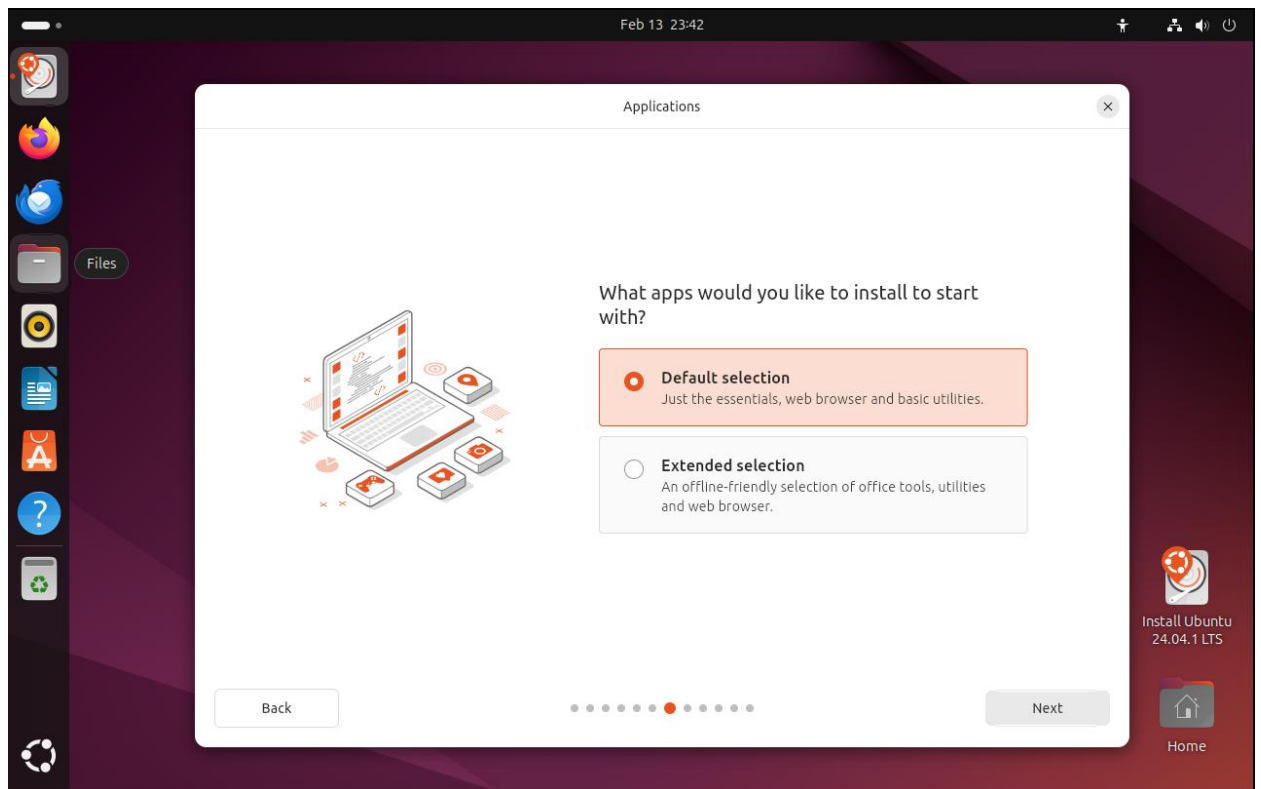

Set up your internet connection, im using wired so ill click next.

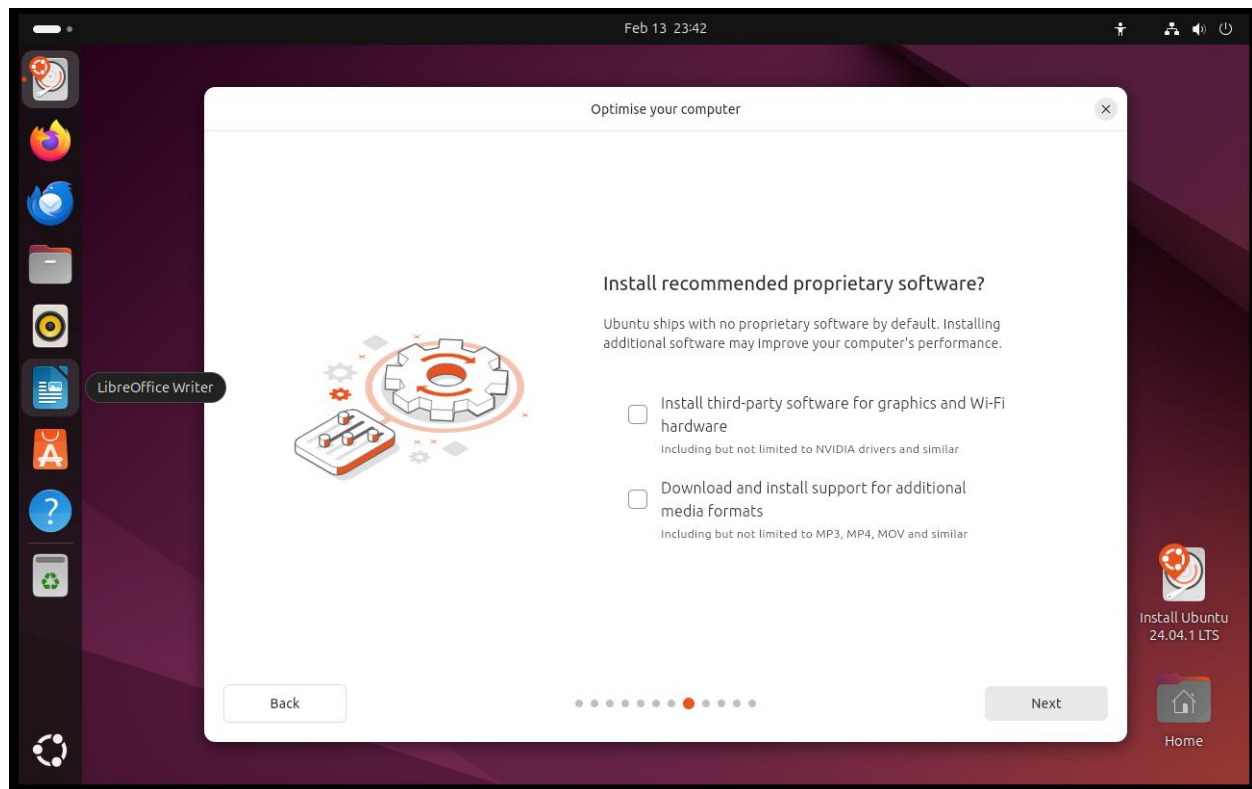

After the network screen your installer might need an update, if so go ahead and update,

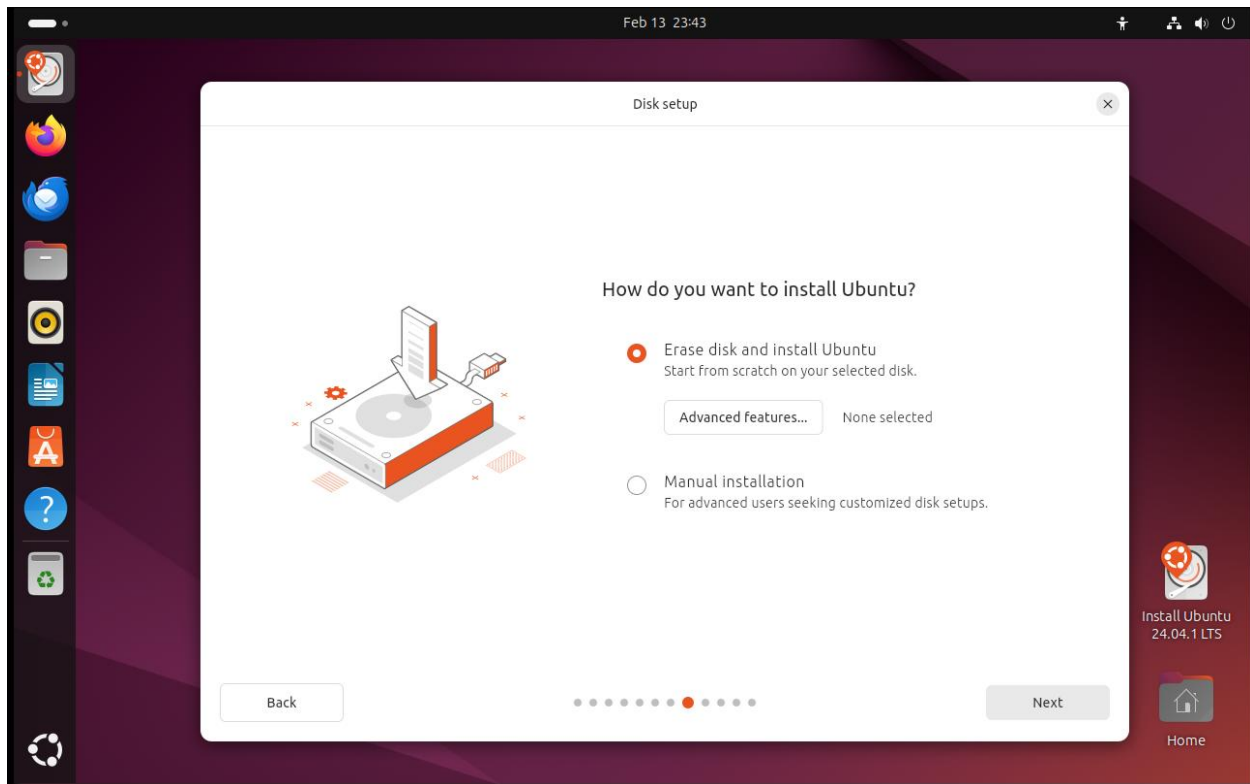

Keep interactive installation selected then click next

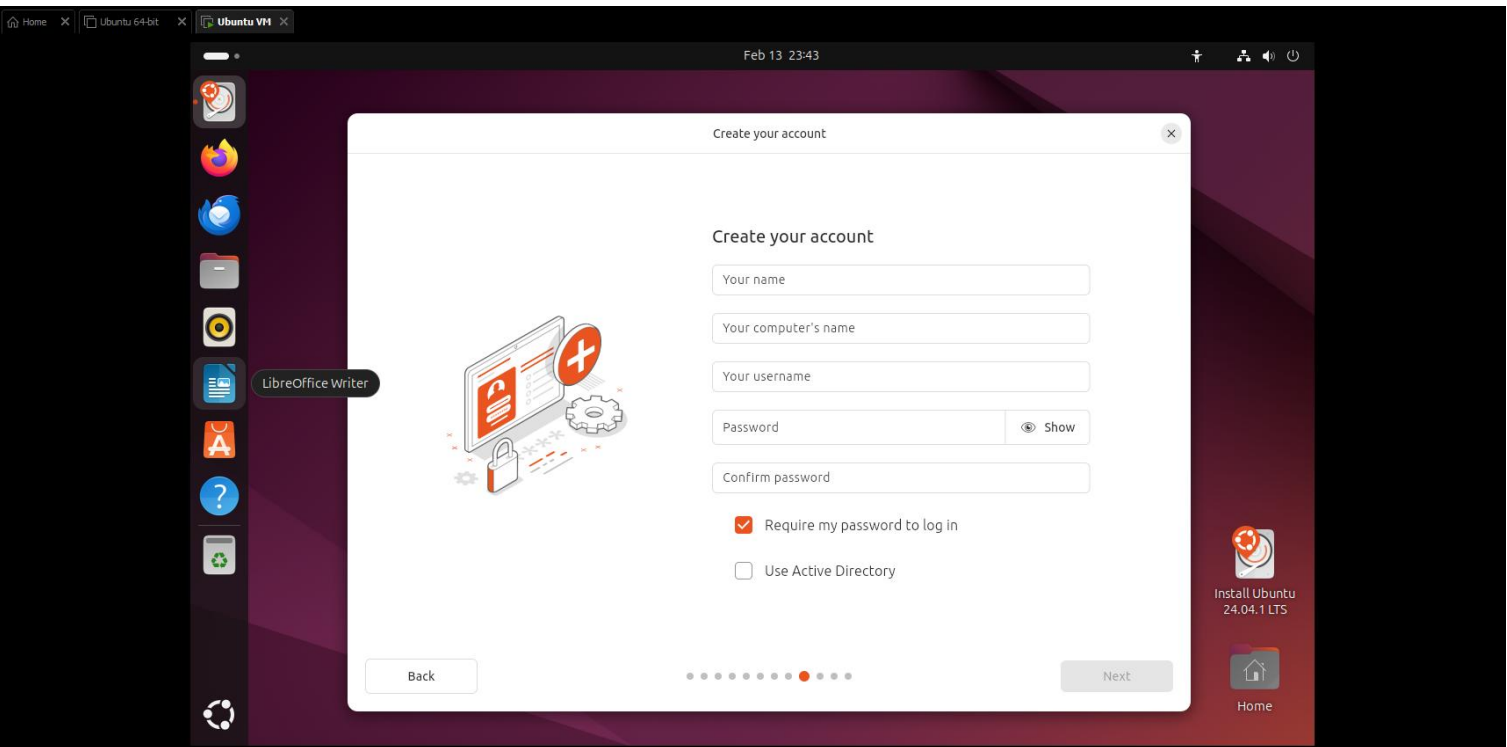

Default selection is barebones, no software preinstalled for you, you would have to install the software yourself which is no big deal. So I'm keeping default selected for this installation. Click next after you've decided.

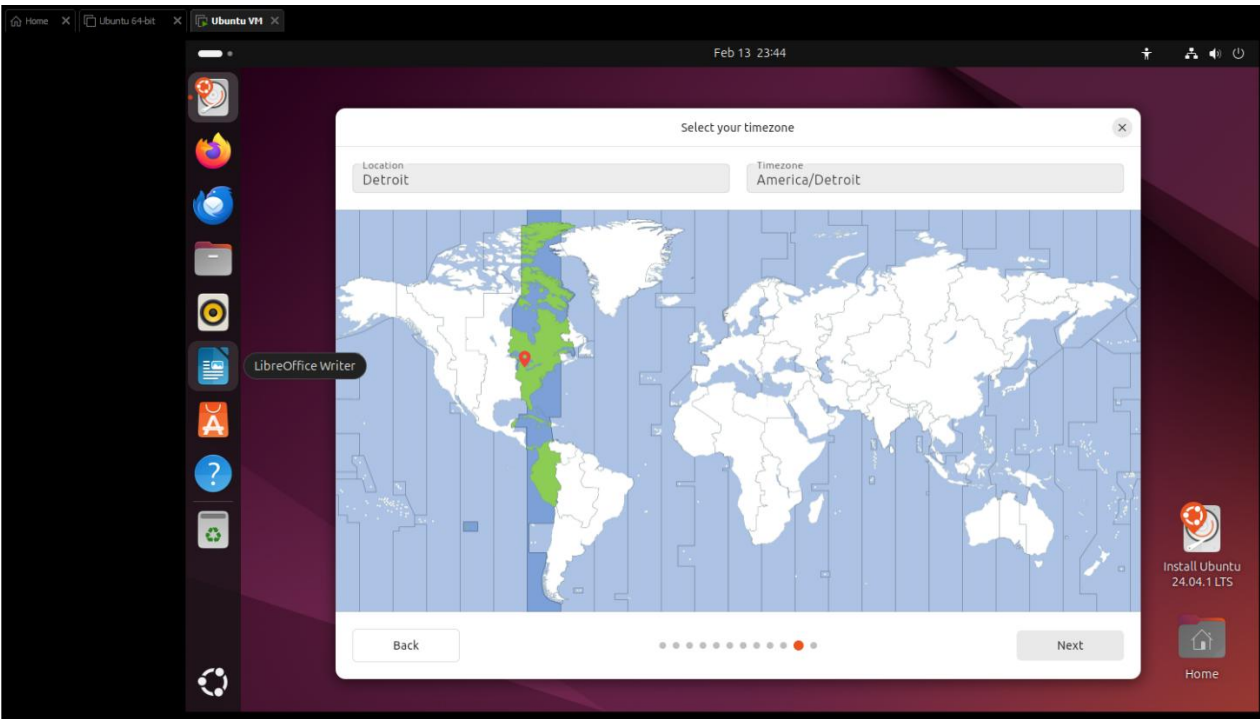

This will install any graphics drivers you may want if you would use this as a personal computer, also .MP4 support, im gonna keep both boxes unchecked. Click next after you've made a decision.

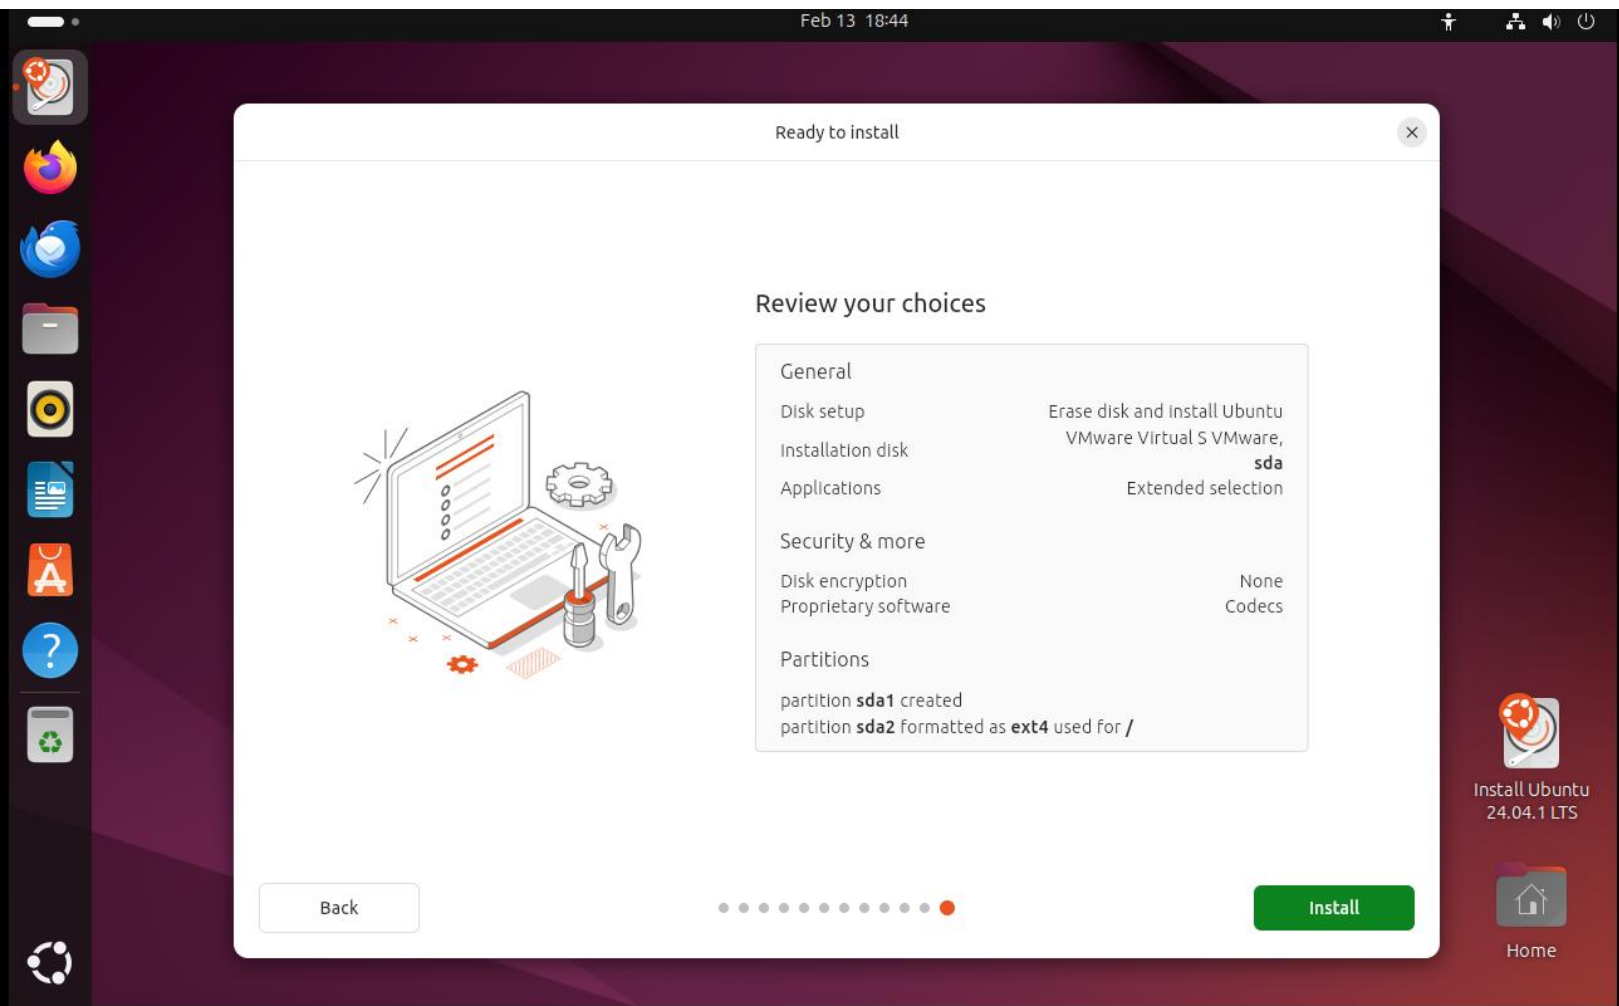

For VM's just keep the first option checked and click next. This will erase anything that's on the virtual disk and install a fresh Ubuntu OS. (it will not be erasing anything since this is a clean install)

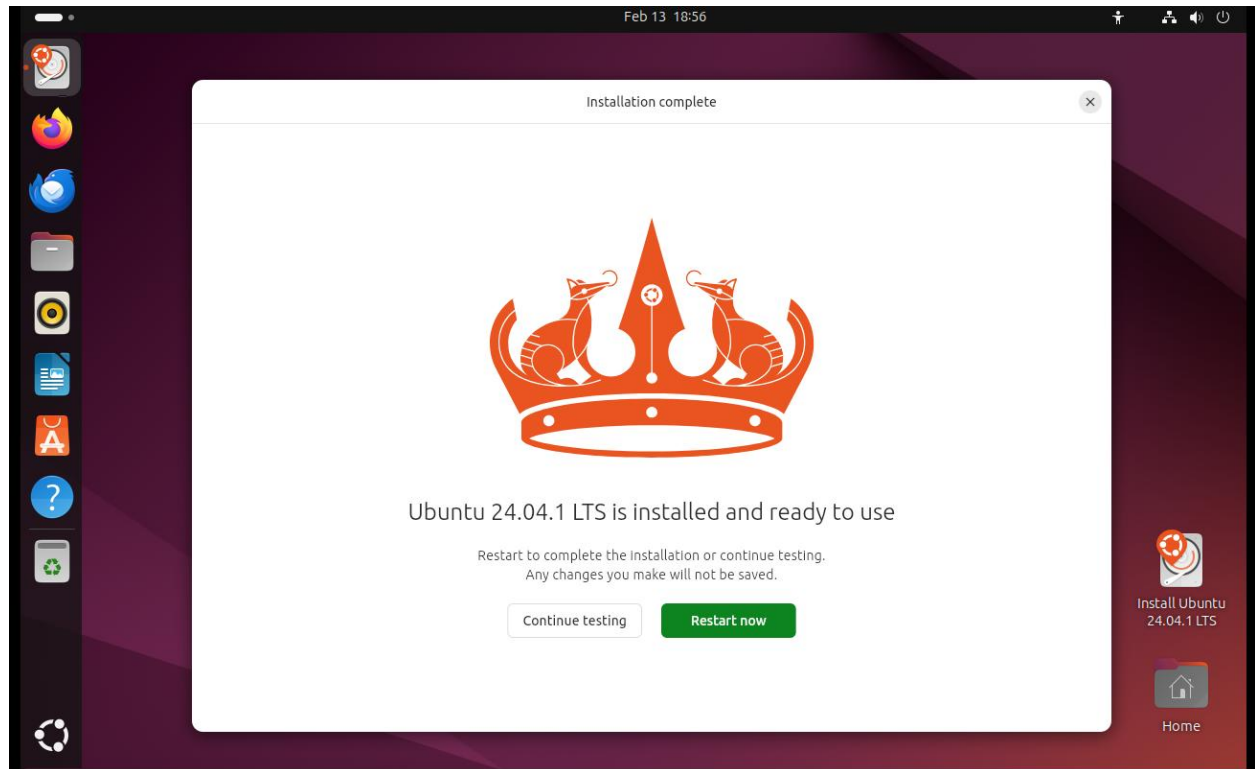

Create a user account. After filling the forms click next.

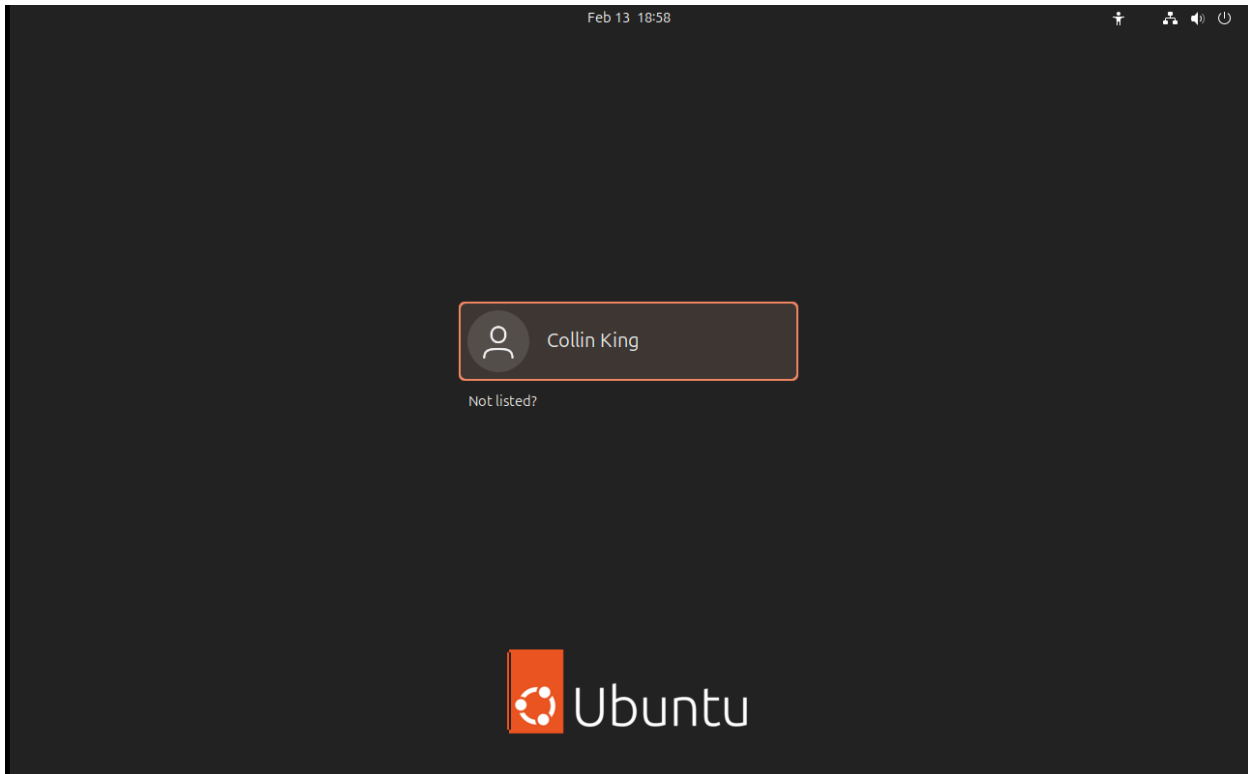

After making the account you must select the time zone you're in, click on the location with your mouse then click next.

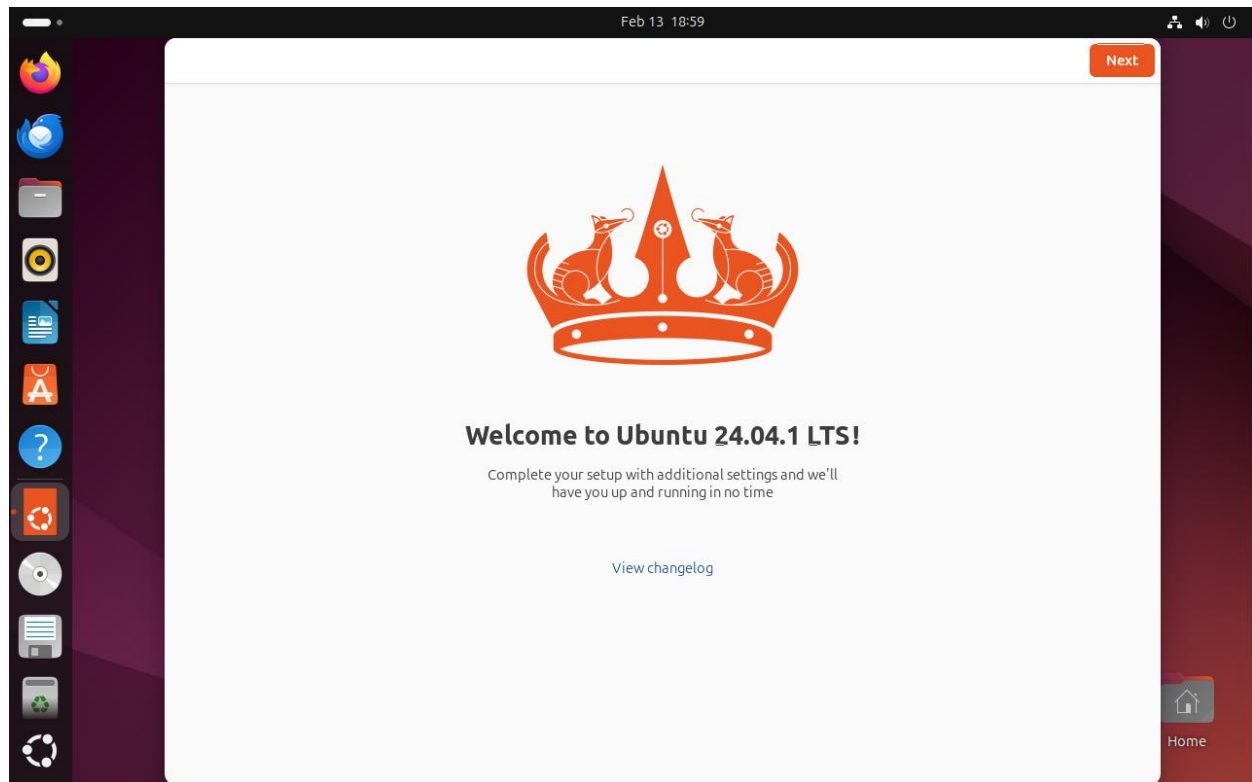

This screen is confirming the install, review the settings you've put on the installation, if you're happy with the settings, click the green install button.

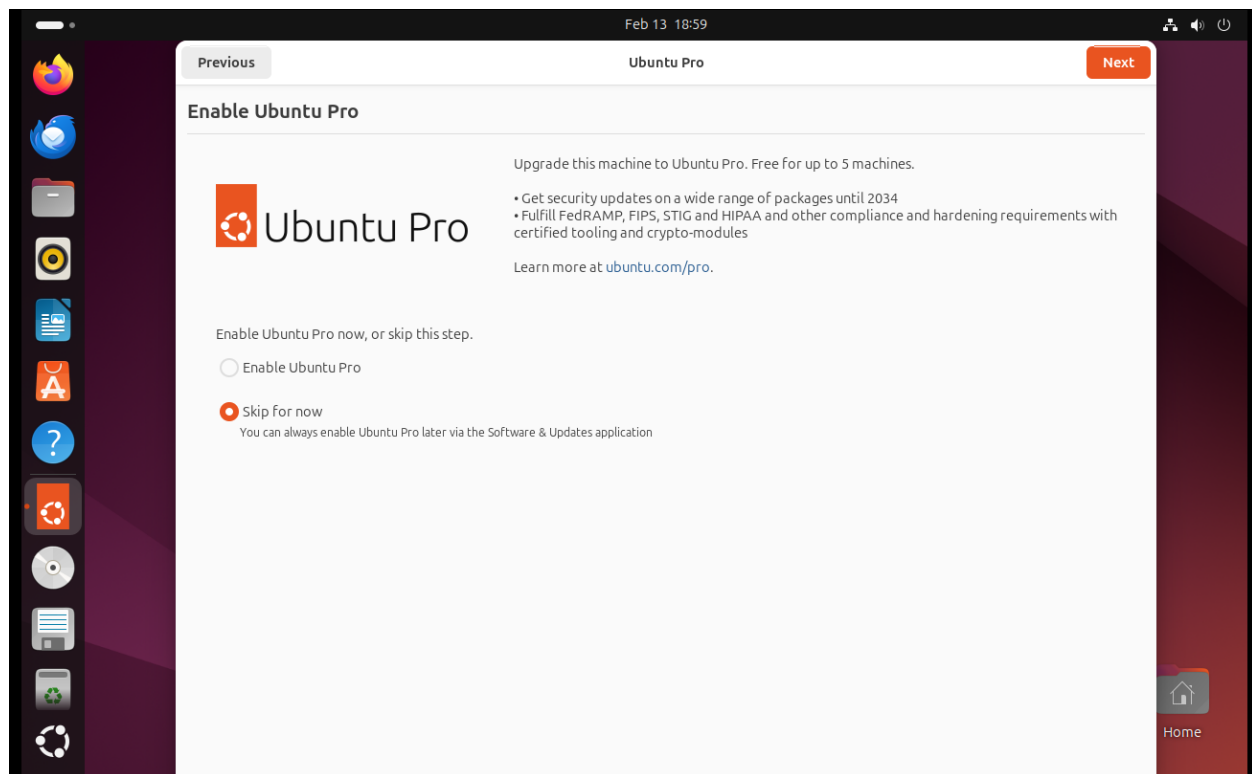

You can either keep testing out the OS, or click restart now to complete the installation.

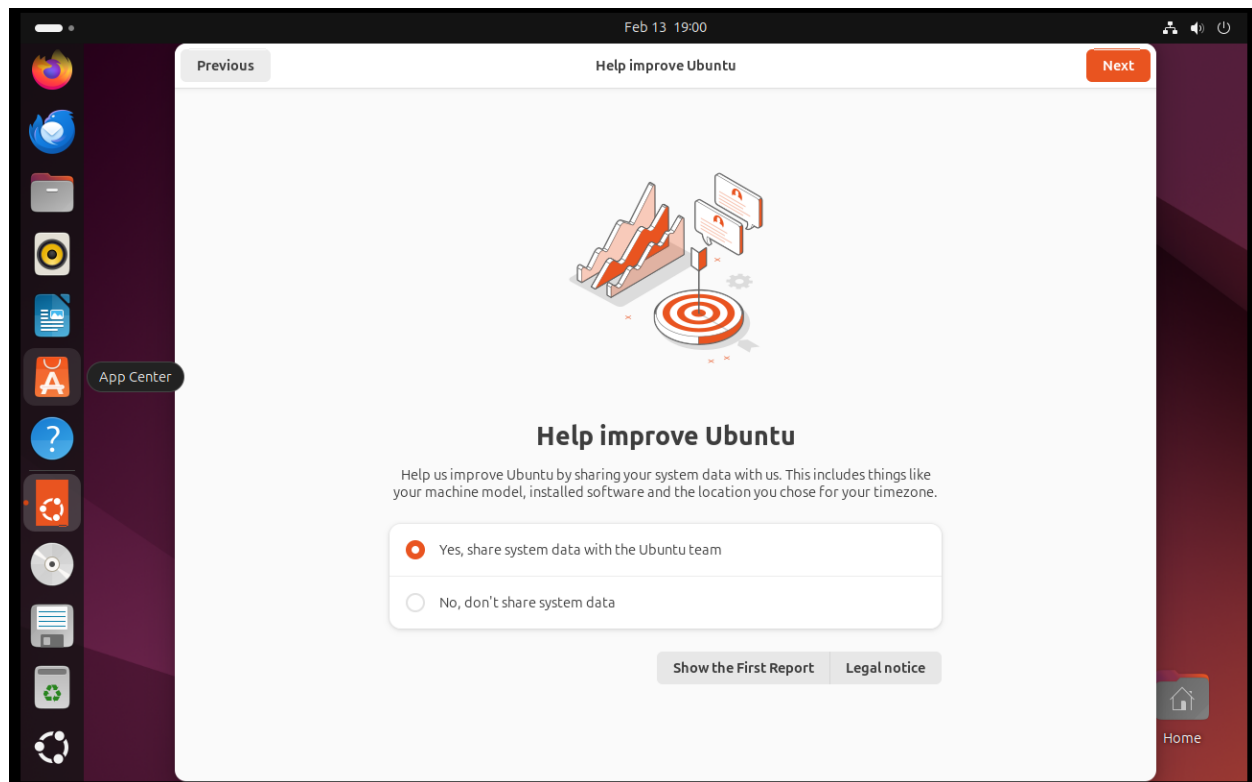

This will be your user account selection screen, click on the account you've made and log in.

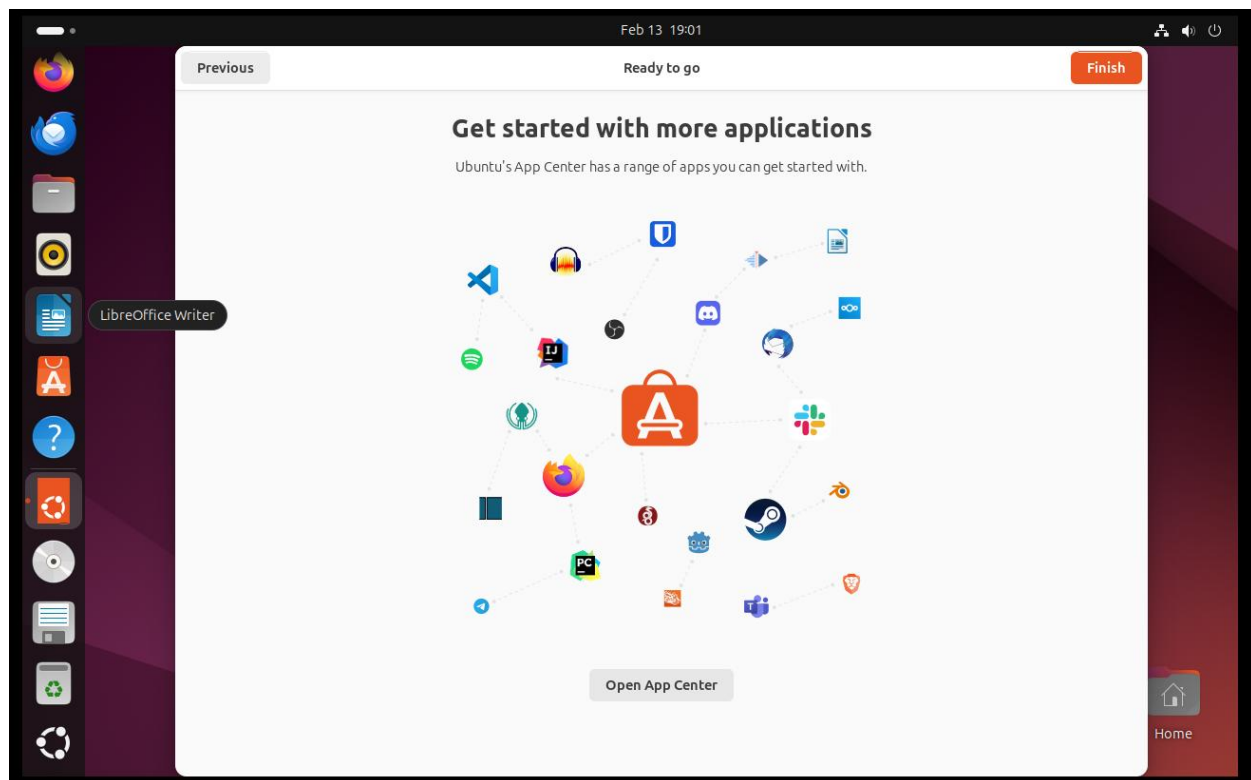

You'll be greeted with this screen!

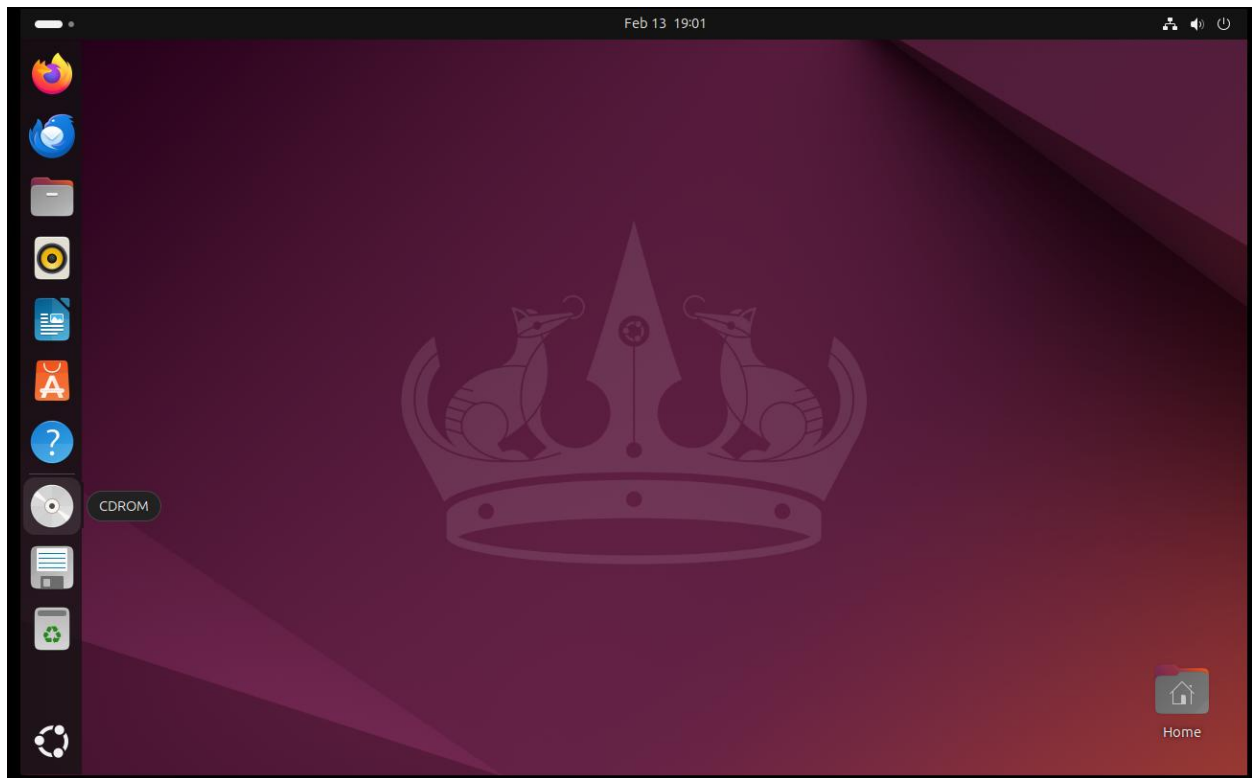

This is Ubuntu Pro, it is probably recommended you use Ubuntu Pro as updates will last for the next 10 years, and regular support for Ubuntu halts in July 2025 (This year!!!) the updates contain bug fixes and security updates so I would do it, I didn't during this process but I'm going to go back and activate it.

You can either chose to send system data to Ubuntu or not, click next at the top after you've made a decision.

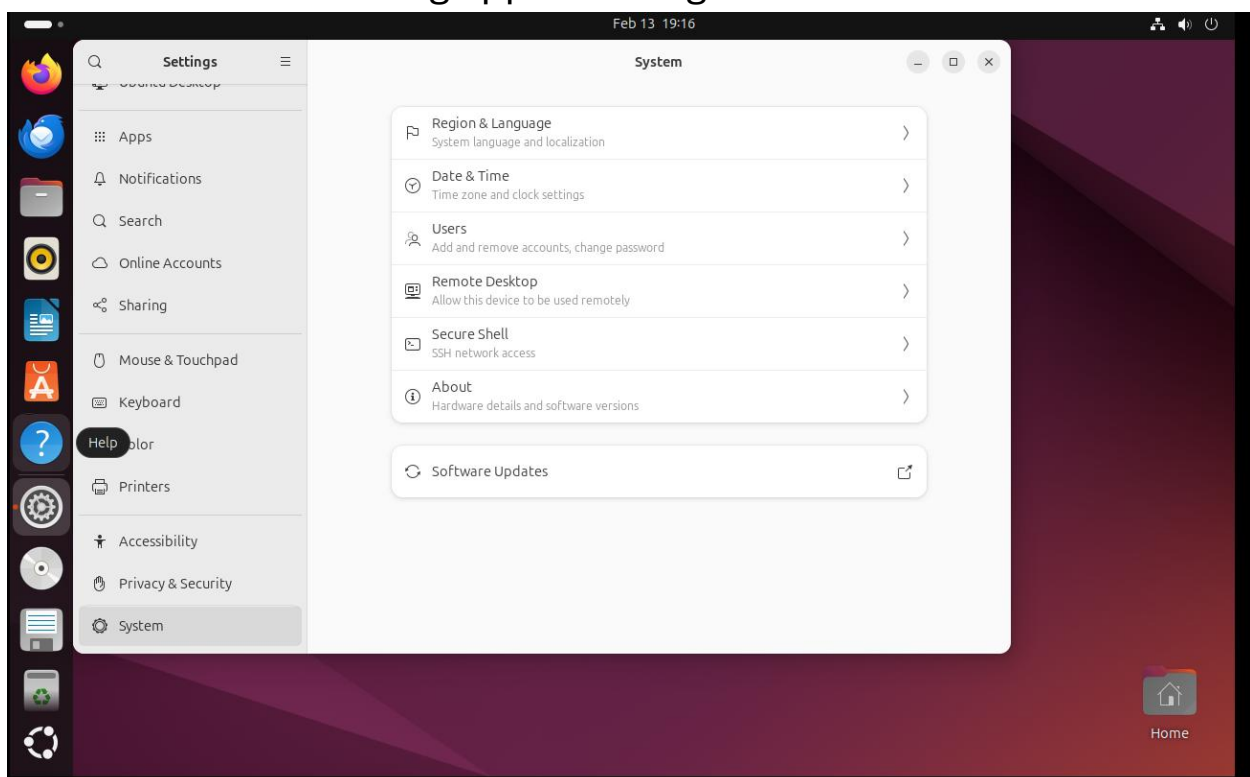

This is showing you the app center, anything you need on the VM will be in the app center for you, for the most part there shouldn't be much internet downloading unless you use the command line to install programs. Click next after this screen.

Install completed! Great! Now let's look at our hardware, at the bottom left you'll see the open apps menu, click on it.

Then click on the setting app on the right side of the screen.

On the left side, scroll all the way down to “System”

After clicking “System” look at the bottom of the page to see “System details” click on that then your screen should look like the screenshot below. Notice my ram is not 2GB like how it was configured before, I’ve always had to put my VM’s at 4GB at least (even without the other tab opened) So if you notice the VM isn’t working right, I would start with memory in the VM Shell.
